ACKNOWLEDGMENTS

To Doctor M. E. Mundel for his guidance, constructive criticism, and inspiration from beginning to end.

To the Staff and members of the 1950 Purdue Motion and Time Study Work Session for a real day's work, wholeheartedly given.

To the Administrative Records Section for the many time and labor-saving IBM procedures.

To my wife, Jeanne, for her continuing assistance with the many "arrays" and other procedures.

And lastly, to the many critics and "deep" thinkers who provided a necessary stimulation of thought throughout.

ACKNOWLEDGMENTS

To Professor W. S. Washburn for his guidance,
constructive criticism, and inspiration from
beginning to end.

To the staff and members of the IRLC for
their help and kind words for a real day's
work, unhesitatingly given.

To the administrative people for
the easy time and labor-saving IRLC procedures.

To my wife, Jeanne, for her continuing
assistance with the many "errands" and other
duties.

And finally, to the many critics and "dear"
criticisms who provided a necessary stimulation of
thought throughout.

ABSTRACT

"...time study...may be defined as a procedure for determining the amount of time required, under certain standard conditions of measurement, for tasks involving some human activity."¹ One of the most important phases of a time study is that of rating the job pace or rate of activity. It is here that judgment on the part of the rater plays a major role. The major objective of this thesis is to examine the current state of time-study rating.

A group of seventy-two raters, nearly all active time study engineers, gathered at the 1950 Purdue Work Session, were the cross-section of the profession whose work furnished the basis for this study.

A series of eighteen films, three paces each of six different actual industrial jobs, were shown in entirely random order of pace and job. Each rater assigned ratings exactly as if the jobs were being performed in his own plant, according to his own company standard and company policies. These ratings were converted by him to a common, comparable, numerical basis to facilitate further analysis.

Previous to the showing of the films, personal data questionnaires were individually filled out, thus providing the necessary information for assembling the data according to various parameters.

...this study... may be defined as a procedure for determining the amount of time required, under various standard conditions of measurement, for tasks involving some human activity. One of the most important phases of a time study is that of rating the job pace or rate of activity. It is here that judgment on the part of the rater plays a major role. The major objective of this thesis is to examine the current state of time-study rating.

A group of seventy-two raters, nearly all active time study engineers, gathered at the 1950 Purdue Work Session, were the cross-section of the profession whose work furnished the basis for this study.

A series of eighteen films, three scenes each of six different actual industrial jobs, were shown in entirely random order of pace and job. Each rater assigned ratings exactly as if the jobs were being performed in his own plant, according to his own company standards and company policies. These ratings were converted by him to a common comparable, numerical basis to facilitate further analysis.

In view of the showing of the films, personal data questionnaires were individually filled out, thus providing the necessary information for assembling the data according to various parameters.

J. E. Womack, Method and Time Study Principles and
Principles, New York, Macmillan Co., 1930, p. 1.
 from Macmillan.

The data so obtained was³¹² arranged and computations made in such a manner as to permit of analysis as to consistency, accuracy, and amount of variation. Also, it was desired to ascertain what outstanding differences, if any, might be found with regard to the following parameters: years experience, concept of standard, initial training, size of rater's own plant, geographic area, and size of city in which plant is located.

The ratings on each film were arrayed for the whole group and by each subdivision of the major parameters. Consistency is a measure of how the individual ratings are grouped about their arithmetic mean; accuracy, of how they are grouped about a least-squares corrected mean.

In order to carry out the other objectives, it became necessary to find an additional basis for comparison between the various parameter subdivisions, this basis to be capable of consolidation of much bulk into a few statistics that will submit to further analysis. Thus, for each array, limits were set up at the $\pm 5\%$, $\pm 7\frac{1}{2}\%$, $\pm 10\%$, and the $\pm 20\%$ levels about the actual means to measure consistency, and similar limits were set about the corrected means to measure accuracy. Percentages of each array lying within each set of limits were then determined, becoming the figures for comparison.

For consistency of rating, within $\pm 5\%$ of the group mean we find an average of 38.2 percent or nearly two out of five, which increases to 64.9 percent, nearly 2 out 3,

The data so obtained were presented and comparisons made in such a manner as to permit of analysis as to consistency, accuracy, and amount of variation. Also, it was desired to ascertain what outstanding differences, if any, might be found with regard to the following parameters: years experience, amount of standard, initial training, size of person's own plant, geographic area, and size of city in which plant is located.

The ratings on each film were analyzed for the whole group and by each subdivision of the major parameter. Consistency in a measure of the individual ratings are given about their arithmetic mean; accuracy, or how they are grouped about a least-squares corrected mean.

In order to carry out the other objectives, it became necessary to find an additional basis for comparison between the various parameter subdivisions, this basis to be capable of consolidation of each walk into a few statistics that will permit of further analysis. Thus, for each rating, limits were set up at the 10%, 15%, 20%, and 25% 100% levels about the actual means to measure consistency, and similar limits were set about the expected means to measure accuracy. Percentages of each rating type within each set of limits were then determined, becoming the figures for comparison.

For consistency of rating, within 15% of the group mean we find an average of 55.8 percent or nearly two out of five, which increases to 64.9 percent, nearly 3 out of 5,

within $\pm 10\%$. The results for overall group accuracy are somewhat lower, ranging from 1 in 3 within $\pm 5\%$ to nearly 3 out of 5 within $\pm 10\%$ of the corrected mean.

The average range of the ratings of pace for the whole group, still based on 100 as standard, is found to be 77 - 154, exactly a 2 to 1 spread. The average rating to which such an average range applies is 113 percent of standard.

It is felt that this analysis of "current practice" time-study rating shows that the present state of time-study rating is not up to the level required for the widespread confidence and acceptance that is so necessary for its use. The need for time studies and their proven aid in solving many complex industrial problems have been demonstrated for many years. The need now is for more consistent, accurate, and reliable ratings of pace and their end product, more absolute, trustworthy, and authoritative standard times.

AN ANALYSIS OF CURRENT-PRACTICE, UNAIDED,
TIME-STUDY RATINGS

INTRODUCTION

"...time study...may be defined as a procedure for determining the amount of time required, under certain standard conditions of measurement, for tasks involving some human activity."¹ The end result of a time study is the standard time for the job. One of the most common types of time study is the stop-watch time study, by far the most widely used aid in obtaining a standard time,² as defined by Mundel: "A stop-watch time study is used to find the amount of time that will be necessary to perform a unit of work, using a given method, under given conditions of work, by a worker possessing sufficient skill to perform the job properly, as physically fit for the job after adjustment to it as the average person who can be expected to be put on the job and working at a pace 100/130 of the maximum pace that can be maintained, day after day, without harmful physical effects."³

It is obvious that it would be mere chance to find a

TIME-STUDY METHODS

INTRODUCTION

"...time study... may be defined as a procedure for determining the amount of time required, under certain specified conditions of measurement, for tasks involving some human activity. The end result of a time study is the standard time for the job, one of the most common types of time study is the stop-watch time study, by far the most widely used in obtaining a standard time, as defined by L. B. Gilbreth: "A stop-watch time study is used to find the amount of time that will be necessary to perform a unit of work, using a given method, under given conditions of work, by a worker possessing sufficient skill to perform the job properly, as typically fit for the job after adjustment to it as the average person and can be expected to be put on the job and working at a pace 100/150 of the maximum pace that can be maintained, day after day, without undue physical effort."

It is obvious that it would be safe to say that

1. L. B. Gilbreth, Methods and Time Study (Chicago and New York, Practice-Pull, Inc., 1930, p. 1).

2. "How Time is Lost," Modern Management, Vol. 6, No. 4, May 1935, pp. 17-19.

3. L. B. Gilbreth, Systematic Motion and Time Study, New York, Practice-Pull, Inc., 1937, p. 126.

worker satisfying all the above conditions and working at such a standard pace. The mechanics of comparing a given worker's pace to standard pace is called rating. It is here that the rater's judgment must play an important part as no precise, mathematical way of comparison has yet been successfully devised.^{4, 5} This phase of time study, rating, should be the strongest link in the chain because its veracity and fairness must be apparent if the standard time so produced is to be accepted with trust and confidence by all concerned.

There are many systems of rating, nearly all relying entirely on judgment. How well this judgment is used, what basis it rests upon, and the manner in which it takes into account the various factors of skill, aptitude, and degree of exertion are extremely important quantities in making a consistent, reliable and fair rating. Many systems have evolved using an estimate of effort to which individual company fatigue, personal time, tool repair, etc. allowances are added.

The actual item which must be judged is pace or rate of activity. The standard rate of activity on a particular job is chosen as that pace desired to be maintained. There are many numerical designations of standard pace

4. M. E. Mundel, Op. Cit., p. 155.

5. L. P. Alford and John R. Bangs, Production Handbook, New York, The Ronald Press Co., 1947, pp. 505-507.

worker's activity in the above-mentioned and working as
 such a standard case. The economic of comparing a given
 worker's case to standard case is called rating. It is done
 that the worker's judgment must play an important part as in
 practice, mathematical way of comparison has not been suc-
 cessfully devised. This case of time study, rating,
 should be the strongest link in the chain because it is
 really the process must be repeated if the standard also
 so produced is to be accepted with trust and confidence by
 all concerned.

There are many systems of rating, nearly all rating
 entirely on judgment. How well this judgment is made, what
 basis is used upon, and the manner in which it comes into
 account the various factors of skill, aptitude, and degree
 of exertion are extremely important questions in making a
 consistent, reliable and fair rating. Many systems have
 existed under an estimate of error to which individual
 company ratings, personal time, tool repair, etc. also
 have been added.

The actual item which must be judged is made up of
 of activity. The standard rate of activity on a particu-
 lar job is chosen as that best adapted to be maintained.
 There are many numerical designations of standard case

4. H. B. Sargent, Op. Cit., p. 125.

 New York, The Ronald Press Co., 1934, pp. 203-207.

such as 60, 78, 80, 100, 120, etc. Each has its own peculiar means of manipulation to assist in arriving at a standard time.

Just how well industry is accomplishing the task of rating is a primary factor in the entire success, acceptance, and use of time study. It is a matter of importance to management and labor alike. As one prominent trade unionist states it: "Thus the solution to the basic problem of the validity of existing time study practice lies at the very heart of satisfactory industrial relations."⁶ Thus, in just one example of the uses of time study, management and labor bargaining collectively, such bargaining should not and must not rest on a chance basis of inaccurate and inept ratings and their attendant poorly allocated standard times. Similarly, the many other uses of time studies must not rest upon any insecure or wavering basis.

6. William Gomberg, A Trade Union Analysis of Time Study, Chicago, Science Research Associates, 1948, p. 15.

each as 60, 70, 80, 100, 120, 150, 200. Each has its own peculiar
 means of manipulation to assist in arriving at a standard
 time.

Just how well industry is accomplishing the task of
 yielding a primary factor in the economic success, prosper-
 ity, and the rate of time study. It is a matter of importance
 to management and labor alike. As one prominent trade
 unionist states: "There are solutions to the basic problems
 at the vicinity of existing time study practice lies in the
 very heart of satisfactory industrial relations." Thus, in
 just the example of the use of time study, management and
 labor bargaining collectively, each bargaining should not
 and will not rest on a chance basis of incidents and in-
 stitutions and their attendant poorly allocated standards
 time. Similarly, the more other uses of time studies must
 and rest upon any measure or working basis.

G. Elliot Gordon, A Trade Union Analysis of Time Study,
 Chicago, Illinois Research Association, 1936, p. 12.

OBJECTIVE AND PURPOSE

The objective of this thesis is to gather and array data on current practice time-study ratings in such a manner that will permit of analysis as to consistency, accuracy, and amount of variation. These three factors in the rating of job pace or rate of activity are extremely important necessities for the widespread acceptance of and confidence in time study work. Just how well does present practice of time study engineers deserve such confidence and acceptance? It is hoped that a partial, though limited, answer to this question may be found in this paper.

Many experienced time study engineers have stated that estimates of pace rarely vary more than five percent.⁷ How reliable is this estimate of raters' abilities? Are management and labor justified in taking action based on such an estimate of consistency?

It was further desired to ascertain what outstanding differences, if any, might be found with regard to the following parameters: (1) years of experience of the rater; (2) concept of standard individually used; (3) type of training initially received; (4) size of rater's own plant; (5) geographic area in which the rater's plant is located; and (6) the size of town or city in which the individual rater's plant is located. Taking into account the region

7. Dale Yoder, Personnel Management and Industrial Relations, New York, Prentice-Hall, Inc., 1948, p. 143.

The objective of this study is to gather and analyze data on current practices in the study of activity and efficiency. It is hoped that a partial, though limited, answer to this question may be found in this paper.

Many experienced time study engineers have agreed that estimates of work rates vary from 10 to 20 percent. The manager who is this estimate of rates, activities, and management want and labor justified in taking action based on such an estimate of consistency.

It was further desired to ascertain what outstanding differences, if any, might be found with regard to the following parameters: (1) years of experience of the worker; (2) concept of standard individually used; (3) type of training initially received; (4) size of worker's own plant; (5) geographic area in which the worker's plant is located; and (6) the size of town or city in which the individual worker's plant is located. Taking into account the region

7. Dale W. Taylor, Scientific Management and Industrial Rate-
Study, New York, Prentice-Hall, Inc., 1911, p. 127.

drawn upon, and in the hope of most logically uncovering the existence of or lack of any differences, the above parameters were subdivided as follows:

- (1) Years Experience
 - (A) less than six months
 - (B) 6 months - 2 years
 - (C) 2 - 4 years
 - (D) more than 4 years

- (2) Concept of Standard Used at Plant
 - (A) your own concept of standard performance
 - (B) some film or other embodiment of standard performance.

- (3) Initial Time Study Training Received
 - (A) Company
 - (B) College

- (4) Size of Plant
 - (A) 0 - 200 employees
 - (B) 200 - 1,000 employees
 - (C) over 1,000 employees

- (5) Plant Geographic Location
 - (A) Northern Midwest (less Michigan)
 - (B) Central Midwest
 - (C) Southern Midwest
 - (D) Michigan

Green Book, and in the hope of more fully understanding the
situation of or lack of any of them, the above parameters
were submitted as follows:

- (1) Years Experience
 - (a) less than six months
 - (b) 6 months - 1 year
 - (c) 1 - 2 years
 - (d) more than 2 years

- (2) Concept of Leadership Used as Basis
 - (a) form an concept of standard performance
 - (b) some use of other embodiment of standard performance.

- (3) Initial Firm Study Technique Received
 - (a) Company
 - (b) College

- (4) Size of Firm
 - (a) 0 - 200 employees
 - (b) 201 - 1,000 employees
 - (c) over 1,000 employees

- (5) Firm Geographic Location
 - (a) Western Midwest (Iowa, Michigan)
 - (b) Central Midwest
 - (c) Eastern Midwest
 - (d) Atlantic

(6) Size of City, Plant Located in

- (A) 0 - 5,000
- (B) 5 - 10 thousand
- (C) 10 - 25 thousand
- (D) 25 - 50 thousand
- (E) 50 - 100 thousand
- (F) over 100,000.

- (a) 100,000 - 0
- (b) 100,000 - 10
- (c) 100,000 - 20
- (d) 100,000 - 30
- (e) 100,000 - 40
- (f) 100,000 - 50

[The following text is extremely faint and illegible. It appears to be a series of paragraphs or a list of items, but the content cannot be discerned.]

PROCEDURE A
PREPARATION FOR AND RECEIPT OF RATINGS

Six films were obtained from a large southern Indiana industrial concern. Each film consisted of several cycles at different paces of a particular, actual industrial job. After a careful check for spurious motions, constancy of pace, and of cycle times, three film loops were cut from each film. These eighteen film loops, each of exactly one cycle, became the jobs which were to be rated. No false experimental conditions are thus set up because previous research has shown that time study engineers can rate pace from films or by actually observing the worker with practically equal facility.⁸ These jobs covered the range from simple finger, hand, and arm movements of light assembly and inspection to the gross body movements used in loading and operating a large forming press.

The next necessary component, the raters themselves, were the participants at the Fifth Annual Motion and Time Study Work Session (1950 session) held at this university. These seventy-two raters were from throughout the Middle West and nearly all were actively engaged time study engineers.

A short briefing of the assembled engineers was made prior to the showing of the films. It was emphasized that

PREPARATION FOR AND NATURE OF RATINGS

His film was obtained from a large southern Indiana industrial concern. Each film consisted of several cycles at different rates of a particular, actual industrial job. After a careful check for various motions, consistency of pace, and of cycle times, three film loops were cut from each film. These eighteen film loops, each of exactly one cycle, became the jobs which were to be rated. In this experimental condition are that set up because previous research has shown that the study engineers can take pace from films or by actually observing the worker with practically equal facility.⁶ These jobs covered the range from simple finger, hand, and arm movements of light assembly and inspection to the gross body movements used in load-lift and operating a large forklift truck.

The next necessary component, the raters themselves, were the participants at the fifth Annual Session and the Study Work Session (1950 session) held at Yale University. These seventy-two raters were from throughout the Middle West and nearly all were actively engaged in study engineering.

A short briefing of the assembled engineers was made prior to the showing of the films. It was emphasized that

B. E. Knudsen and J. E. Warkentin, Members of the Research Council on Human Factors, "The Study Work Session," 1950.

the various jobs and paces of these jobs were to be rated exactly as if they were occurring and being rated in the rater's own plant. Ratings were assigned according to the rater's own company standard and company policies and were then converted to a common, comparable, numerical basis by each individual rater. The common basis selected was the 100 standard-130 maximum non-harmful physical effort definition. The raters were furnished a simple, arithmetic conversion table to convert their own rating scale, no matter what standard, to this scale.

The work session was cautioned not to rate the method, to assume the method used the best for the particular job in question. No method variations were given on any of the jobs and the raters were told to assume that work of acceptable quality accompanied each of the eighteen performances.

The assemblage was further cautioned that although there were three paces each of six different actual industrial jobs, there was no set ratio between paces on the same or different jobs; and that the three paces of each job, themselves, might be practically the same or quite different.

Finally the films were shown, and in an entirely random order so that no set sequence of pace or job could possibly influence the raters. Although shown in random order, the films are numbered consecutively from one to eighteen in this paper, each three numbers in order

the various jobs and cases of cases jobs were to be tested exactly as if they were occurring and being tested in the order of their own kind. Ratings were assigned according to the order of the company standards and company policies and were then converted to a common, comparable, numerical scale by each individual tester. The common scale selected was the 100 (100-150) maximum non-physical physical effort scale. The ratings were furnished a clinical, arithmetic conversion table to convert their own rating scale, to another scale, to this scale.

The work session was outlined and to rate the ratings, to ensure the method used was best for the particular job in question. No method variations were given on any of the jobs and the ratings were told to assume that work of a certain quality accompanied each of the fifteen performance.

The assignments were further contained that although there were three under each of six different actual industrial jobs, there was no set ratio between pieces in the case of different jobs; and that the three pieces of each job, however, might be practically the same or quite different.

Finally the films were shown, and in an arbitrary fashion order as that to set assurance of pace or job could possibly influence the ratings. Although shown in random order, the films are numbered consecutively from one to eighteen in this paper, each three numbers in order.

referring to the three paces of a particular job.

The information enabling the breakdown of the six major categories into their several subdivisions was obtained from personal data questionnaires filled out prior to the showing of the films.⁹

At this point it is desired to state that the manner in which the ratings were recorded and tabulated has much to do with the size and scope of the analyses of this work. Each rater placed his converted ratings on an IBM mark-sensing card which then later was punched and used to assist in tabulating the results. The facility with which the various ratings and parameters could be entered on these cards, the speed and accuracy of assembling all or any segment of the data by any particular parameter or subdivision, and the complete tabular arrays, all produced by the various IBM equipments are an outstanding addition to this type of research. Long, tedious hours of data assemblage and arraying became short minutes to the electronic "mind".

 Thesis, Manuscript, Boston, Mass., 1930.

PROCEDURE B
ASSEMBLY AND COMPUTATION OF DATA

A logical division of the procedure occurs at this point. The first phase included the preparation for and the receipt of the "current practice" ratings of pace by the group of time study engineers. The second phase consists of the proper assemblage, manipulation, and computation of the data necessary to form the basis for any possible results and conclusions.

The individual ratings assigned to a particular film were next arrayed for the whole group (all 72 raters) and by the various subdivisions of the six parameters. For each array, the average or arithmetic mean was determined as the initial basis for comparison. Consistency, the analysis of which was one of the primary objectives, is the measure of how the individual ratings of a given array are grouped about its arithmetic mean.

However, to call this "average rating" the actual or true rating, even though it is the concensus of opinion of 72-odd professional time study men, would be an untenable assumption. Much previous information on the subject has determined a general tendency to rate the slower paces too high and the more rapid paces too low.¹⁰ Therefore, a corrected mean, or rather, a best available approximation

EXPERIMENTAL DESIGN
ANALYSIS AND CONCLUSIONS

A random selection of the specimens occurs at this point. The first phase included the preparation for and the receipt of the "random question" testing of each by the group of three study engineers. The second phase consisted of the proper assembly, maintenance, and repair of the data necessary to form the basis for the analysis results and conclusions.

The individual ratings assigned to a particular film were not averaged for the whole group (all 75 ratings) and by the various subdivisions of the film categories. For each rating, the average or arithmetic mean was determined as the initial basis for comparison. Consequently, the analysis of which was one of the primary objectives, is the measure of how the individual ratings of a given group are grouped about the arithmetic mean.

However, to call this "average rating" the actual of the rating, even though it is the arithmetic mean of 75-odd professional film study men, would be an inadequate assumption. Such previous information on the subject has determined a general tendency to rate the slower pace too high and the more rapid pace too low.¹⁰ Therefore, a corrected mean, or rather, a best available approximation

10. W. S. Arnold and D. V. Benbow, Results of the Group Film Study and the Study Film Rating, Journal of the American Psychological Association, 1947.

of the correct mean rating, was computed with the aid of a precise knowledge of the ratios between cycle times for each of the three paces on a given job. A consistent series based on the actual cycle times for each pace was obtained for each of the six different jobs. The consistent series was adjusted by a single factor so that when this series and the averages of the individual ratings in each array on each job were then plotted, the sums of the squares of their deviations about $Y=X$ were a minimum. A value, so obtained, thus becomes the best approximation of the correct mean rating, hereafter referred to as the corrected mean. Accuracy, whose analysis was another primary objective, is the measure of how the individual ratings of an array are grouped about its corrected mean.

It is apparent that the term "array" has assumed an ever-increasing importance in this paper, reoccurring most frequently. To yield a clearer picture of what is referred to when this word appears, the following is offered in explanation. The ratings for a particular pace by a particular subdivision of a parameter, such as "2 - 4 years" of "Years Experience", are arranged from lowest to highest. This is an array. For each array the range, lowest subtracted from the highest rating; the arithmetic mean, the corrected mean, and various groupings about these means may be easily computed. The importance of arrays in this work may be further emphasized by the quick calculation that, having eighteen paces and twenty-two subdivisions of

parameters, a resultant 396 arrays must necessarily be arranged and manipulated.

In order to carry out the other objectives, it becomes necessary to find an additional basis for comparison between the various parameter subdivisions. This basis to be capable of consolidation of much bulk into a few statistics that will submit to further analysis. Thus, for each array, limits were set up at the $\pm 5\%$, $\pm 7\frac{1}{2}\%$, $\pm 10\%$, and the $\pm 20\%$ levels about the actual means to indicate comparative consistency of rating, and similar limits were set about the corrected means for an indication of comparative accuracy. Percentages of each array lying within each set of limits were then determined and are tabulated in the various Tables in the Appendix. The average percentage for each group also appears.

Reference to any of the Tables mentioned above will show quite wide variations in percentages between the various subdivisions of a parameter. The next step was to determine if any statistically significant differences actually existed. A standard F test was made for significant differences at either the 5 or 1 percent confidence levels between means within a parameter. For those that indicated a difference in means greater than could be expected by chance alone, Fisher t tests between all combinations of pairs within a parameter were made. Results of the t test at the 5% level indicated a reasonable doubt that the differences between two means could be due to

parameters, a significant 95% change was necessary on at-
least one parameter.

In order to carry out the other objectives, the fol-
lowing procedure was used: an additional series of comparisons
between the various parameter combinations. The data to
be analyzed of comparison of each pair from a two series
was first analyzed by further analysis. Then, for each
series, limits were set at the 10%, 15%, 20%, and the
10% level about the actual means to indicate comparative
significance of period, and similar limits were set about
the corrected means for an indication of comparative sig-
nificance. Percentages of each series lying within each set of
limits were then determined and are tabulated in the vari-
ous tables in the appendix. The average percentages for
each group are shown.

Before any of the tests mentioned above will
show definite side relations in relationships between the
various subdivisions of a parameter. The next step was
to determine if any statistically significant differences
actually existed. A standard test was made for signifi-
cant differences between the two series in a particular confidence
level. A standard means within a parameter. For these data
indicated a difference in means greater than could be ex-
pected by chance alone, that is, tests between all com-
binations of pairs which a parameter were made. Results
of the test as the 10% level indicated a significant change
that the difference between two means could be due to

chance alone; while results at the 1% level indicated quite probably, i.e., 99 times out of 100, that the differences were due to some factor other than chance. The results of both the F and t tests appear in Tables 24 and 25 respectively.

RESULTS

Probably the most important results appear in Tables 1 and 2 of the Appendix. These portray the various findings for the work session taken as a whole. For consistency of rating, within $\pm 5\%$ of the group mean we find an average of 38.2 percent, or nearly two out of five, which increases to 64.9 percent, nearly 2 out of 3, within $\pm 10\%$. The results for overall group accuracy are somewhat lower, ranging from 1 in 3 within the $\pm 5\%$ limits to nearly 3 out of 5 within $\pm 10\%$ of the corrected mean.

The average range of the ratings of pace for the whole group, still based on 100 as standard, appears in Table 2 as 77 - 154, exactly a 2 to 1 spread. The average rating to which such an average range applies is 113 percent.

Also found in Table 2 are the eighteen arithmetic and corrected means and the variations between each, ranging from 0 on film 15 to 12.9% on film 9, showing an average variation of 6.2%.

Tables 3 through 23 show the percentages within the limits of their respective means for the various subdivisions of the six parameters. From these tables, with the aid of Tables 24 and 25, the following statistically significant differences between means are found:

Initial Training. Between "Company" and "College" for both consistency and accuracy.

... ..

Probably the most important results appear in Tables 1 and 2 of the appendix. These tables show the various findings for the work session taken as a whole. For consistency of rating, within 1% of the group mean we find an average of 38.8 percent, or nearly two out of five, which increases to 64.9 percent, nearly 3 out of 5, within 10%. The results for overall group accuracy are somewhat lower, ranging from 1 in 3 within the 1% limit to nearly 3 out of 5 within 10% of the corrected mean.

The average range of the ratings of pass for the whole group, still based on 100 as standard, appears in Table 2 as 77 - 104, exactly a 2 to 1 spread. The average rating to which such an average range applied is 115 percent.

Also found in Table 2 are the eighteen arithmetic and corrected means and the variations between each, ranging from 0 on film 13 to 13.9% on film 9, showing an average variation of 8.2%.

Tables 3 through 23 show the percentages within the limits of their respective means for the various subdivisions of the six parameters. From these tables, with the aid of Tables 24 and 25, the following statistically significant differences between means are found:

Initial Training, between "Company" and "College"

for both consistency and accuracy.

Area. Between Michigan and all other groups in consistency only.

Size of City. Between over 100,000 and all other groups in consistency only.

Between 5 - 10,000 and all groups but 0 - 5,000 in consistency.

Between 0 - 5,000 and 25 - 50,000 in consistency.

Because of the industry, attitude, and whole-hearted cooperation of the members of the 1950 work session, it is believed that the results and data compiled in this thesis are probably representative of time study practice in the Middle West area.

free. Between Michigan and all other groups in non-
state only.

CONCLUSIONS

1. The premise that time study engineers' ratings of pace rarely vary more than 5 percent is not borne out. Only 38.2 percent of the work session were within $\pm 5\%$, and no subdivision had more than 56.7 percent within these limits of its mean.

2. The average range of 77 - 154 on an average pace of 113 percent appears excessive in that all raters were viewing the same films at the same time. However, it should be pointed out that 89.7 percent of the whole group were within $\pm 20\%$, yielding a range of 90 - 135 (about 113) in which 9 out of 10 raters are found.

3. The group as a whole exhibited a marked tendency to rate the faster paces more consistently than the slower. On the slowest pace shown (film 4 - 97 percent) only 17 percent of the work session participants were within $\pm 5\%$ of the mean rating, while on a typical faster pace shown (film 12 - 134 percent) a total of 53 percent were within $\pm 5\%$ of the mean. This effect continued with only 48 percent of the group within $\pm 10\%$ of the mean rating on the slowest while 81 percent were within these limits of the mean rating on the faster pace.

4. Throughout the analysis, accuracy, or grouping about the best available estimate of the correct pace, was slightly inferior to consistency (the grouping with respect to the arithmetic mean pace).

1. The present study indicates that the practice of using a single mean rating for the entire group is not always justified. Only 52.2 percent of the work sessions were within 1SD, and no individual had more than 52.7 percent within these limits of the mean.

2. The average range of 77 - 154 on an average pace of 113 percent appears excessive in that all ratings were within the same limits as the pace class. However, it should be pointed out that 82.9 percent of the whole group were within 1SD, yielding a range of 90 - 122 (lower 1SD) in which 9 out of 10 ratings are found.

3. The group as a whole exhibited a marked tendency to rate the faster paces more consistently than the slower. On the slowest pace shown (film 4 - 87 percent) only 17 percent of the work session participants were within 1SD of the mean rating, while on a typical faster pace shown (film 12 - 124 percent) a total of 53 percent were within 1SD of the mean. This effect continued with only 48 percent of the group within 1SD of the mean rating on the slowest while 81 percent were within these limits of the mean rating on the faster pace.

4. Throughout the analysis, accuracy, or grouping about the best available estimate of the correct pace, was slightly inferior to consistency (the grouping with respect to the arithmetic mean pace).

5. Also apparent in the many arrays is the previously mentioned "regression" tendency to rate the lower paces too high and the higher paces too low.

6. No significant differences at the 5% confidence level between the various subdivisions of the EXPERIENCE, CONCEPT OF STANDARD, and NUMBER OF EMPLOYEES categories is found. However, it is desired to point out that a comparison of Tables 7 and 8 will show that the raters having a "Film or other embodiment of standard" concept are both more consistent and more accurate within all rating error limit groups, having percentage pluralities ranging up to 11 percent.

7. Significant differences between means existed at the 5% confidence level (1 time) and at the 1% level (5 times) for consistency between "Company" and "College" under category INITIAL TRAINING (see Table 25). In each instance "College" is lower than "Company" when comparing actual percentage means. It is not believed that the inference that receiving initial time study training in college is inferior to company initial training can be sustained from this one category breakdown analysis, but rather that the possible interaction of other parameters such as years of experience, size of group, etc. have played an important part in yielding these results.

8. Under the AREA parameter, significant differences at the 1% confidence level were found between "Michigan" and all other subdivisions for all groupings. Reference

Also apparent in the many errors is the previous-
mentioned "regression" tendency to rate the lower passage
too high and the higher ones too low.

6. No significant differences at the 5% confidence
level between the various subdivisions of the "College"
category or "Company", and "College" category is
found. However, it is desired to point out that a comparison
of Tables 7 and 8 will show that the rates having a
"firm or other method of standard" concept are both
more consistent and more accurate within all rating error
limit groups, having percentage differences ranging up to
11 percent.

7. Significant differences between means existed at
the 5% confidence level (1 tailed) and at the 1% level (2
tailed) for consistency between "Company" and "College"
under category INITIAL TRAINING (see Table 12). In some
instances "College" is lower than "Company" when comparing
actual percentage means. It is not believed that the in-
ference that receiving initial time away training is col-
lege is inferior to company initial training can be sus-
tained from this one category breakdown analysis, but
rather that the possible interaction of other parameters
such as years of experience, size of group, etc. have
played an important part in yielding these results.

8. Under the 10% parameter, significant differences
at the 1% confidence level were found between "College"
and all other subdivisions for all groupings. Reference

to the tables of actual percentage means shows "Michigan" possessing markedly lower averages throughout. However, the results here are not an indictment of the whole "Michigan" area as the sample size of only nine men is very small and two of this subgroup assigned extremely high ratings throughout the entire eighteen films.

9. Under SIZE OF CITY the raters from "Over 100,000" are significantly and consistently below all other groups. Likewise are the "5 - 10,000" raters below nearly all others. Again, it is believed that probably the extremely small sample sizes of these two groups and the interaction of other factors preclude the definite conclusion that inferior ratings correlate with such sizes of cities.

to the table of actual percentages shown below "Michigan" possibly markedly lower averaged throughout. However, the results here are not an indication of the whole "Michigan" area as the sample size of only nine was a very small and even of this nature assigned extremely high ratings throughout the entire eleven films.

Under this ON CITY the rates from "Over 100,000" are significantly and consistently below all other groups. Likewise are the "2 - 10,000" rates below nearly all others. Again, it is believed that probably the extremely small sample sizes of these two groups and the inclusion of other factors preclude the definite conclusion that inferior ratings correlated with such sizes of cities.

The following table shows the correlation between the size of the city and the rating given to the film. The correlation is very high, and it is believed that the correlation is due to the fact that the larger the city, the more likely it is to have a higher rating. This is probably due to the fact that the larger the city, the more likely it is to have a higher rating. This is probably due to the fact that the larger the city, the more likely it is to have a higher rating.

INFERENCES

1. It is felt that this analysis of "current practice" time-study rating shows that the present state of time-study rating is not up to the level required for the widespread confidence and acceptance that is so necessary for its use. The need for time studies and their proven aid in solving many complex industrial problems have been demonstrated for many years. The need now is for more consistent, accurate, and reliable ratings of pace and their end product, more absolute, trustworthy, and authoritative standard times.

2. Perhaps the single most important inference that can be gained from this analysis is that there exists an urgent need for removing or minimizing the personal "judgment" factor from the individual rating. The wide ranges of ratings when viewing the same rates of activity must be lessened if we are to achieve more consistent ratings.

The use of different concepts of standard pace and the reliance on personal judgment must be minimized. In other words, a more concrete basis must be found for the rating procedure. It is believed that the exception noted under Specific Conclusion 6, while not conclusive in itself, points the way to possible ultimate reduction to insignificance of the judgment factor. It is suggested that the use of a film showing a standard rate of activity or various percentages thereof, shown adjacent to or

DISCUSSION

1. It is felt that this analysis of "current prac-
 tice" time-study rating shows that the present state of
 time-study rating is not up to the level required for the
 widespread confidence and acceptance that is so necessary
 for its use. The need for time studies and their proper
 use in solving many common industrial problems have been
 demonstrated for many years. The need now is for more con-
 sistent, accurate, and reliable ratings of pace and quality
 and product, more absolute, trustworthy, and authoritative
 standard times.

2. Perhaps the single most important inference that
 can be gained from this analysis is that there exists an
 urgent need for removing or minimizing the personal "judge-
 ment" factor from the individual ratings. The wide ranges
 of ratings when viewing the same rates of activity must be
 lessened if we are to achieve more consistent ratings.

The use of different concepts of standard pace and
 the reliance on personal judgment must be minimized. In
 other words, a more concrete basis must be found for the
 rating procedure. It is believed that the exception noted
 under Specific Conclusion 6, while not conclusive in it-
 self, points the way to possible definite reduction in
 insignificance of the judgment factor. It is suggested
 that the use of a film showing a standard rate of activity
 or various percentages thereof, shown adjacent to or

superimposed upon a film of the pace desired to be rated can result in much more consistent, accurate, and reliable ratings of pace by giving the rater a visible, concrete basis on which to exercise the then modicum of personal judgment required. While this procedure may not be economically feasible for the making of all job pace ratings, a judicious use of such a procedure should, in all probabilities, result in a definite minimizing of the judgment factor.

reported upon a film of the case desired to be read
 can result in such more consistent, accurate, and reliable
 ratings of cases by giving the raters a visual, concrete
 basis on which to evaluate the then history of personal
 judgment required. While this procedure may not be ac-
 curately feasible for the making of all job descriptions,
 a judicious use of such a procedure would, in all prob-
 ability, result in a definite minimizing of the judgment
 factor.

The following is a list of the factors which are
 considered in the rating of a job description. These
 factors are:

1. Knowledge
2. Skill
3. Ability
4. Experience
5. Education
6. Training
7. Physical
8. Mental
9. Emotional
10. Social
11. Personality
12. Attitude
13. Motivation

APPENDIX

The first part of the document discusses the general principles of the proposed system. It outlines the objectives and the scope of the project, emphasizing the need for a comprehensive and integrated approach to the problem at hand. The text highlights the importance of collaboration and communication among all stakeholders involved in the process.

The second part of the document provides a detailed description of the system's architecture and components. It explains how the various elements of the system are interconnected and how they work together to achieve the desired outcomes. This section includes a thorough analysis of the system's strengths and weaknesses, as well as a discussion of the potential risks and challenges that may be encountered during implementation.

APPENDIX

The following section contains supplementary information that supports the main body of the document. It includes a list of references, a glossary of key terms, and a series of tables and figures that provide additional data and insights into the system's performance and characteristics. These elements are intended to provide a more complete and detailed understanding of the project and its findings.

The first table in the appendix presents a summary of the system's performance metrics over a period of six months. The data shows a steady improvement in efficiency and a reduction in error rates, indicating that the system is meeting its intended goals. The second table provides a breakdown of the system's costs and benefits, demonstrating a clear positive return on investment.

The figures in the appendix illustrate the system's impact on various stakeholders and its overall contribution to the organization's success. They show that the system has not only improved internal operations but also enhanced the organization's reputation and competitive advantage in the market.
