ABSTRACT

The Computer Aided Prototyping System (CAPS) was created to rapidly prototype real-time systems to determine early in the development cycle whether system requirements can be met. The CAPS consists of several software tools that automatically generate an executable Ada model of the proposed system. This thesis describes the development of a design database (DDB) for the CAPS. The DDB is an engineering database that contains all information related to a prototype software design. The DDB enhances the CAPS environment and the prototyping paradigm by providing to the designer the functions of storage, retrieval, viewing, and versioning of prototype components.

Garry Lewis is the primary author of chapters I and II and Drew Dwyer the primary author of chapters III and IV. In the joint implementation, Lewis focused on the design database schema and C++/ONTOS issues. Dwyer was responsible for building the command line interface, the hierarchical k-ary data structures and the C++ classes/methods for traversing this structure. Items not covered in the above description were mutually developed.

ACKNOWLEDGMENTS

Sincere thanks to the following contributors of this thesis effort:

To our families:

Words can not express the support, devotion, and patience we received from them. Many thanks for your prayers and encouragement;

Professors Luqi and Valdis Berzins:

For their excellent guidance and support;

Professor Lawrence Williamson:

For his many tireless hours, depth of knowledge, and devotion to the cause;

Captain Patrick Barnes, USAF:

For his overall knowledge of the CAPS system and his development of a user interface for the design database.

Albert Wong and Rosalie Johnson:

For outstanding technical support and encouragement;

Süleyman Bayramoglu:

For his extensive knowledge of Unix and various application programs, and his willingness to impart that knowledge to others.

I. INTRODUCTION

A. SOFTWARE ENGINEERING

Each year billions of dollars are allocated for the development and maintenance of progressively more complex weapons and communications systems [Ref. 1:p. 14]. These systems increasingly rely on information processing using embedded computers systems. Satellite control systems, missile guidance systems and communication networks are examples of embedded systems. Correctness and reliability of these software systems is critical to the reliable operation of national defense systems. Moreover, software development of these systems is an immense task with increasingly higher costs and potential for misdevelopment.

Studies conducted in the early 1970's showed that computer software alone comprised approximately 46 percent of the estimated total DoD computer cost. Of this cost, 56 percent was devoted specifically to embedded systems [Ref. 1:p. 14]. In spite of the tremendous cost, there were examples of software systems produced that exceeded estimated development cost, fell behind the production schedule and were delivered not fully functional.

Software engineering developed in response to the need to design, implement, test, install and maintain more efficiently and correctly larger and more complex software systems. Numerous methodologies have been introduced to support software engineering. The two major approaches which underlie these different methodologies are the phased refinement and prototyping method of development.

The predominant model for current application development is the phased refinement approach. In this approach, all system functionality is specified in the first step of development, and subsequent implementation phases add prescribed design details. This

approach is criticized for its high cost of maintenance, failing to abstract tasks early in the development process, and for complications in system integration. Prototyping, as an evolutionary system development paradigm in which a number of nonstandard concepts work together, promises to achieve effective evolution of integrated hardware/software systems.

Prototyping is the process of developing a scaled-down version of a system to use in building a full-scale system. Computer-aided rapid prototyping promises to provide a means for building a scaled-down version of a system more quickly than using conventional approaches. The final product of the prototyping activity is a working model that can be used for many purposes, such as requirement validation, feasibility study for a complex system, and functional specification of a system design. [Ref. 2:p.9] Figure 1 illustrates the role of prototyping in software development..

The process model differs from the traditional phased approach in that it concentrates on the hard problem of system development, namely; requirement specification, and design rather than coding. Equally important, validation, evaluation, and hardware/software trade-off analysis are all part of the development process--they do not just follow completion of the development in each phase. Rapid prototyping works by providing continuous feedback information as rapidly and efficiently as possible. [Ref. 2:p. 9]

B. THE COMPUTER AIDED PROTOTYPING SYSTEM (CAPS)

The evolution development of a software system design requires an integrated design support environment. A typical structure for a design environment that supports the rapid prototyping paradigm and the evolution process model is that provided by the CAPS[Ref. 4:p. 15].

CAPS is a rapid prototyping environment which includes the ability to prototype hard real-time systems. This approach to rapid prototyping uses a specification language called

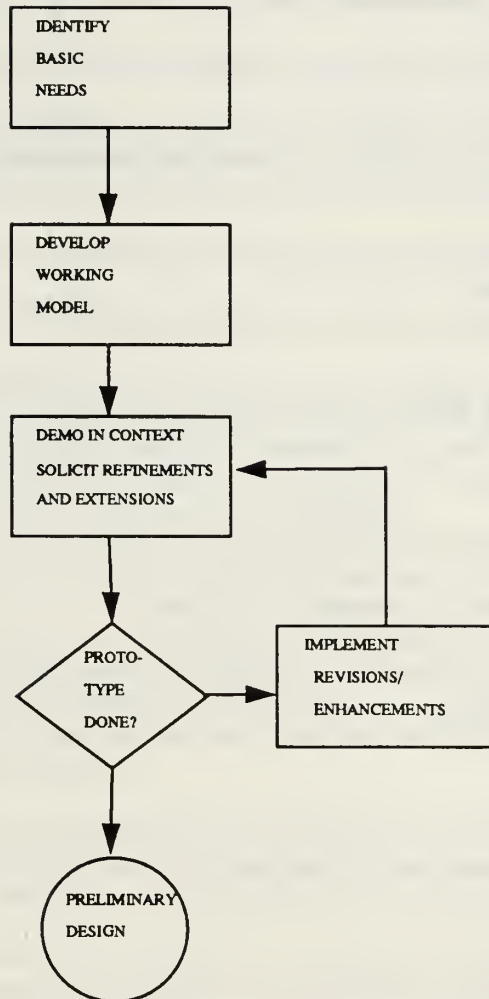

Figure 1. Process Model for Software/System [Ref. 3: p.7]

Prototyping System Design Language (PSDL) and an integrated set of prototyping tools. The tools are integrated through the user interface. The primary tools in CAPS may be divided into three main systems [Ref. 4:p. 15]. The subsystem and their tools are:

The User Interface which is composed of the following tools:

- Graphic Editor
- Syntax Directed Editor
- Browser
- Expert System

The Software Base System which is composed of the following tools:

- Software Design Management System
- Design Database
- Software Base

The Execution Support System which is composed of the following tools:

- Translator
- Static Scheduler
- Dynamic Scheduler
- Debugger

The Graphic Editor is a tool which permits a designer to specify a portion of a PSDL prototype using graphical objects to represent the system. Graphical objects include operators, inputs, outputs, data flows, and self loops on operators. All graphic objects are named and may have time constraints associated with them.

The Syntax Directed Editor is used by the designer to enter the text portions of the prototype design not represented by the graphic editor and to ensure that the prototype is syntactically correct PSDL.

The Browser provides a means for the designer to view reusable components in the software base.

The Expert System provides a paraphrasing capability that generates English text descriptions of PSDL specification. This tool permits users who are unfamiliar with the PSDL language to evaluate a prototype.

The Software Design Management System manages and retrieves the versions, refinements, and alternatives of the prototype in the Design Database and the reusable components in the software base.

The Design Database contains PSDL prototype descriptions for all software projects developed using CAPS.

The Software Base contains PSDL descriptions and implementations for all reusable software components developed using CAPS. [Ref. 5]

The Translator generates high level code from the PSDL prototype which binds the reusable components from the software base to the executable prototype. [Ref. 6]

The Static Scheduler attempts to allocate time slots for the representation of PSDL operators with real-time constraints before the prototype is executed. If the allocation succeeds, all operations are guaranteed to meet their deadlines. [Ref. 7]

The Dynamic Scheduler invokes representation of operators with real-time constraints at run-time to occupy time slots which are not used by operators with real-time constraints. The time slot which the dynamic scheduler uses are “slack times”. Dynamic scheduling occurs during execution of the prototype. [Ref. 7]

The Debugger allows the designer to interact with the execution support system. The debugger has facilities for initiating the execution of a prototype, displaying execution results or tracing information of the execution and gathering statistics about a prototype’s behavior and performance.

Prior to the work described in this thesis, implementations had been developed for the graphic editor, translator, static scheduler, and user interface. The design of a debugger has been defined. Feasibility studies had been conducted for the syntax directed editor, design database and the software base.

C. PROBLEM STATEMENT

Vast amounts of evolving data are created in the design of hard real-time systems. The data must be managed so that it can be stored and retrieved according to the needs of a team of design engineers. In CAPS, the Design Database (DDB) must manage the storage and retrieval of the PSDL program. The DDB must be a specialized DBMS which will store PSDL specifications in a hierarchical format and manage all support files associated with a software design project. [Ref. 8:p. 5]

The DDB also provides concurrency control functions that allow multiple designers to update parts of the prototype without unintentional interference. In the interest of minimizing delay, the design database will not lock out read-only access to any part of the design, even while the design is being updated. Instead, the system will allow examination of the previous version of the component, with a warning that a new version is currently in preparation. On request, the system will provide information about the reason for modification of the component (such as a new or modified requirement).

D. OBJECTIVES

The objective of this thesis is to develop an object-oriented design database for the CAPS. The design database must be accompanied by a user interface that enables the designer to perform routine database tasks such as opening, closing, querying, storing, and retrieving operations.

E. ORGANIZATION

Chapter II contains a survey of the requirements for an engineering database with an emphasis on the object-oriented approach. An introduction to ONTOS, a state of the art object database will conclude Chapter II. Chapter III contains the design of the database objects. Chapter IV shows the design database implementation details using C++ and ONTOS. Conclusions and recommendations will be presented in Chapter V.

II. BACKGROUND

A. ENGINEERING DATABASE

An engineering database should provide the following facilities to support computer-aided software development environments:

- Persistence
- Concurrency control
- Version control
- Reuse of past design objects
- Configuration control
- A wide variety of data storage
- Guarantees data will not be corrupted due to system or media failure

A fundamental feature provided by a database is persistent storage. If objects are persistent, this means the objects in the database will exist after the process that created them has terminated. [Ref. 9:p.472]

In a design environment, one usually has to keep data on several design alternatives, revisions, design stages, and so on. Hence information about the same semantic entity has to be recorded more than once. If versioning is implemented in the DBMS's storage subsystem, then it can be done on fine granularity components. When creating a new version, only those components that have changed since the previous version need to be stored. In the new version, unchanged components can be represented by pointers to their previous versions. This is efficient in storage because only the changed components are repeated in the new versions. It is also efficient in execution time; since versions are not encoded they can be retrieved directly instead of being reconstructed using change logs, as in RCS and SCCS. [Ref. 10:p. 168]

The goals of configuration management include recording the development history of evolving systems, and aiding the management of the systems in guiding and controlling

their evolution [Ref. 11:p. 918]. A structure that captures the evolution of a design in terms of its hierarchical decomposition, alternative implementation and revision history, is crucial to the effective reuse of past design objects.

The partitioning of the design task across levels of abstraction and between many design engineers requires the design database to support concurrent access and implement concurrency controls. The issue of concurrent access for a design is significantly different than for a conventional database application due to the different lengths of transactions that each must support. In a design environment, individual design objects may be “checked-out” for long periods of time [Ref. 12:p. 66]. However, over the course of some transactions other designers may require “access” to a design object that is already checked-out. The concurrency control system must therefore support an object locking mechanism that remains in the database after the current process has ended and permits a designer to view objects already checked out to be operated on by another designer.

The design database must store a variety of formatted, unformatted, and variable-length objects such as program text. In addition to program text, the design database must store management information and natural language descriptions for documentation/historical purposes. One of the criticisms of relational DBMS is that they are inadequate for the data handling requirements of a support environment.

Securing data stored in a design database is another concern [Ref. 13: p. 37]. Some type of mechanism must exist whereby access to objects in the database can be restricted. Protecting high-value data (a civilian company’s proprietary information, or sensitive military data) from compromise requires a system that is sophisticated enough to distinguish different user access privileges and appropriately grant or deny access to a particular object in the database.

Finally the database must ensure that data will not be corrupted due to system or media failures.

B. OBJECT-ORIENTED DATABASE MANGEMENT SYSTEMS

Object-oriented database management systems (OODBMSs) in particular offer several features that promote rapid prototyping. One of the major advantages of the object-oriented paradigm is increased modeling power. Objects and their relationships in OODBMSs can be aligned very closely to objects and their relationships in the real-world. On the other hand, conventional data modeling paradigms such as file formats or relational models require considerable effort to force real-world objects into fixed programming constructs. Thus, a semantic gap exist between the way information is stored and the way it is used. Relational databases, in particular, are inadequate for storing complex information structures such as those in the CAPS. [Ref. 14:p. 32]

OODBMSs typically provide a set of predefined system types, such as set, queue, stack, list, and ordered dictionary. This simplifies the modeling effort as the designer can concentrate on the problem at hand and not clutter the solution with “data structure” specific procedures.

1. Modelling Object Relationships.

Using a limited set of constructs to model diverse concepts inevitably leads to loss of exact meaning. OODBMSs provide several mechanisms to model different relationships among objects. Object specialization/generalization refers to the ability to organize objects in an is-a-kind-of hierarchy. Classification is the ability to relate an object to a group of objects via the is-an-instance-of relationship. Aggregation allows the programmer to model an object as an aggregate of its constituent objects. This type of relationship is known as the is-a-part-of relationship. [Ref. 14:p. 32]

2. Data Abstraction and Data Hiding.

The advent of third-generation programming languages points out the need for a clear distinction between the storage structures associated with the data and the logical structure of the information. Data abstraction refers to the extreme case of this separation, where access to the storage structure may only be gained through a set of predefined operations. Data hiding insulates the programmer from the actual structure where data is stored. In OODBMSs, completely encapsulating an object with its data and operations forces the programmer to use the correct operations on all objects. In addition, a programmer need only know about the objects that his or her code uses. [Ref. 14:p. 33]

3. Property/Operation Inheritance.

Property/operation inheritance implies that an object type automatically has all the properties/operations of its parent type. This is one of the fundamental differences between OODBMSs and relational databases. [Ref. 14:p. 33]

From the standpoint of rapid prototyping, operation inheritance is perhaps more valuable than property inheritance. A programmer does not need to reimplement the behavior that a type shares with its supertype. More importantly, this allows a programmer to assign default behavior to objects. In fact, once the subtype-supertype link is established in the is-a-kind-of hierarchy, a large amount of code automatically become available to the object, even before a single line of code specific to the new object type has been written. [Ref. 14:p. 33]

4. Method and Trigger Combination.

Method and trigger combination invokes writing several small modules of code and using them in different combinations to form methods for different types and situations. In conventional programming, this would involve many checks which would make the code inefficient. However, with OODBMSs, the automatic dispatching mechanisms (see the next section) allows programmers to combine modules by triggering them at the

appropriate places. Each object-specific operation module is designed to handle its additional set of properties and then invoke the corresponding module of its supertype.

5. Generic Programming.

In generic programming, programmers write code modules as general as possible so they can be used by different types of objects. Two essential features of the object paradigm--polymorphism and access to meta-information--help generic programming. Polymorphism is the ability to automatically dispatch a call to an appropriate routine according to the type of parameters passed. This feature makes code upward compatible and resilient to modifications [Ref. 14:p. 34]. Another characteristic of OODBMSs that makes a program resilient to the addition of new types is the accessibility of meta-information. The user-defined types are actually objects compiled into the database. They are therefore available to a program just like any other project. The advanced exception-handling capability of OODBMSs comes in handy in rapid prototyping. Typically, a large amount of code in an application's final version deals with erroneous input data or other anomalous situations. Programmers would like to avoid such detailed error handling in early prototypes. If exceptions are also treated as objects, a programmer can initially write a simple exception handler for the most general type of exception. The programmer can then gradually refine this default exception handler as the prototype grows.

C. ONTOS OBJECT DATABASE

We used the ONTOS Object Database as the database engine for the design database. ONTOS, and its predecessor Vbase, are products of Ontologic, Inc. Vbase was used at the Naval Postgraduate School to test the feasibility of a design database after completion of a conceptual level design [Ref. 8:p. 9].

We conclude this section with a description of the functionality provided by the ONTOS Object Database.

ONTOS supports the full object model. The database schema represents object classes, data members (properties) and member functions (operations). Any class definition which can be specified in C++ can be stored in ONTOS as an ONTOS Type.

ONTOS supports both the single and multiple inheritance model of object oriented programming. The class model that is used in the C++ application is represented in the database as object schema. ONTOS schema information is stored directly in the database as object data.

ONTOS provides three interfaces for use by the application programmer: a C++ interface, an Object SQL interface, and a programmatic schema manipulation facility. We are primarily concerned with the C++ interface. ONTOS provides an interface to C++ which is simple to use. It provides a transparent database interface which is generated by ONTOS utilities.

ONTOS uses a standard client-server architecture. C++ client applications interact with a logical ONTOS database server. The ONTOS database server provides object storage, transactions, concurrency control and other database services. C++ client application make requests to the database server to access and store objects. When a client application requests an object, the system automatically translates the object into its C++ in-memory representation and places the object in the C++ client application's in-memory process heap.

ONTOS provides Aggregate classes including Set, List, Array, and Dictionary. Sets adds the functionality of mathematical sets to C++. Sets are unordered, unkeyed Aggregates with no duplicate members. Lists provide the abstraction of linked list; logically, members are stored serially, in a chain. Each position in the chain is numbered, starting at position zero. An Array is an Association of declared size whose keys are a continuous range of integers and whose members are Entities. Dictionaries are

Associations whose keys and members are Entities and whose size is unrestricted. Dictionaries may be ordered or unordered.

ONTOS supports the standard, locked-based transaction model which is common to all major database systems. The transaction protocol supports transaction start, checkpoint, commit and abort. Checkpoint allows a transaction to commit the changes made up to checkpoint and then to continue with the transaction. ONTOS transactions also support transaction journaling. Journaling maintains a log of changes made to the database within a transaction, which can be used to provide roll-forward recovery after a server process failure.

In addition to the standard transaction model, ONTOS supports high-concurrency and shared transactions for workgroup applications, as well as nested transactions with transaction-based undo capabilities.

Onto supports locking at the level of object, aggregate and page. Object-level locking provides locks on individual objects, thus providing the highest possible concurrency. Aggregate-level locking allows any aggregate of objects to be locked as a group, to provide higher-granularity locking and concurrency control strategies. Page-level locking provides optimum locking performance for large groups of objects physically clustered on disk.

The high level of abstraction provided by C++, together with ONTOS' complete support of the object model, matched against the requirements for an engineering database gave us complete confidence in our choice of tools for implementing a design database for CAPS.

III. REQUIREMENTS SPECIFICATION

Here we define and present a summary of the requirements specification for the DDB. This set of requirements was developed using the Berzins and Luqi model of Software Engineering. This model requires a **problem statement**, development of an **environmental model** and **goals**, and consideration of the **constraints** imposed on the system. [Ref. 9:p. 24]

An additional methodology providing complimentary structure and style is Yourdon [Ref. 15]. In this approach the designer develops an Environmental Model and a Behavioral Model. The environmental model details interactions between the DDB and the user. The users in our model are the tool interface of the CAPS system and the end user (designer). The tool interface responds to the needs and queries of the end user and other tools in the CAPS system. The behavioral model describes the internal mechanisms at work in the DDB system.

A. GOALS

The goals of the DDB are as follows:

- Provide functionality which supports the needs of a prototype designer using the CAPS system.
- Develop a system which encapsulates data and functions together
- Provide flexibility for future development and change

B. DDB INTERFACES

1. Tool Interface

The tool interface is the glue which binds the individual CAPS tools together. A picture containing the tool interface and its relationship to the other tools is provided in Figure 2. The tool interface interprets and reformulates requests sent from one tool to

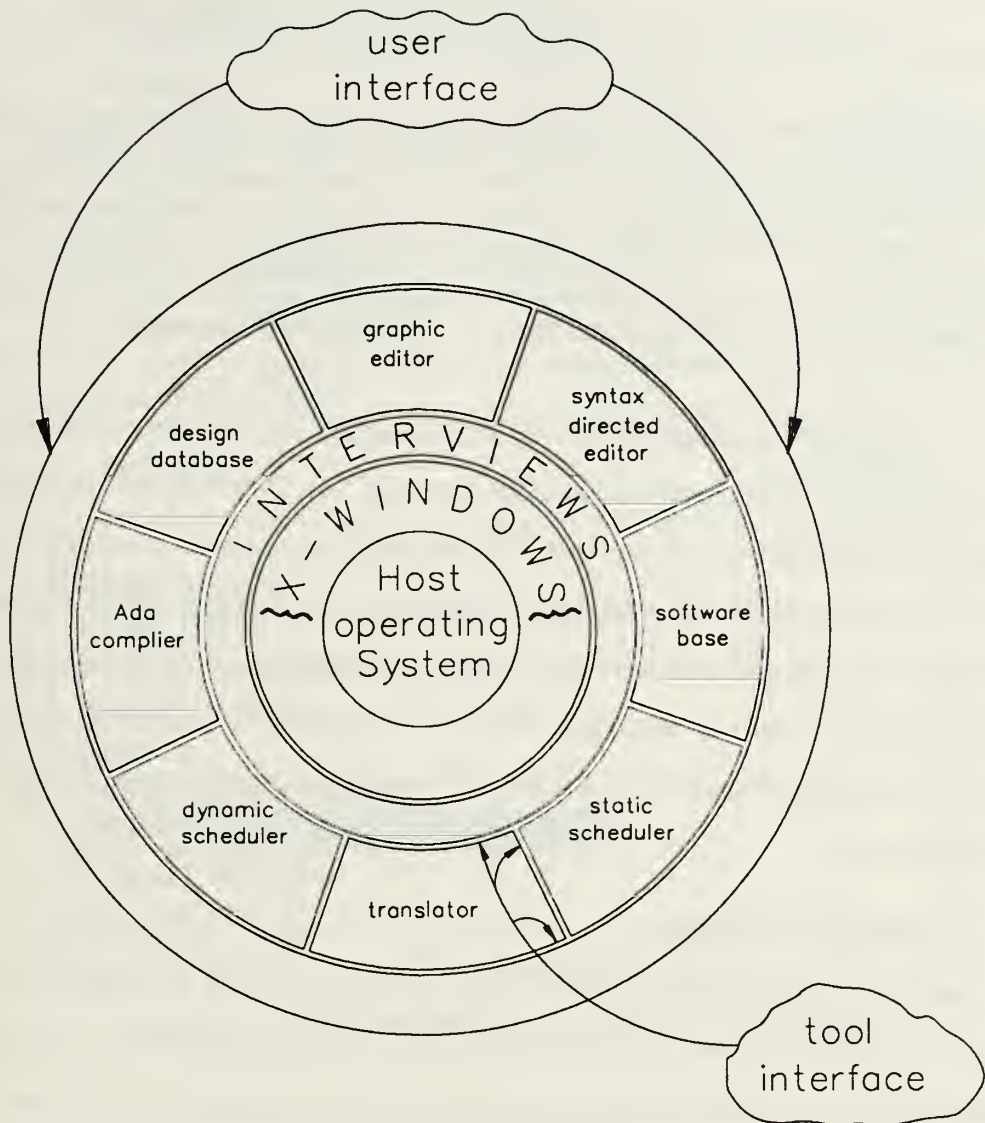

Figure 2. Computer Aided Prototyping Environment [Ref. 3:p. 16]

another - modifying the request to achieve the desired output. A typical sequence of requests is shown in Table 1 in informal language.

TABLE 1: TYPICAL TOOL INTERFACE INTERACTION

Tool	Converses with	Operation
Graphic Editor	Tool Interface	“I want to view operator X”
Tool Interface	Design Database	“Return operator X in Read Mode”
Design Database	Tool Interface	“Operation Complete”
Tool Interface	Graphic Editor	“Resume Operation”

In the previous design of CAPS, if the designer had to communicate with a tool, that tool provided its own end user interface [Ref. 3:p. 21]. However, the DDB responds to commands only from the tool interface. The user interface required to query the DDB and store, retrieve, or manipulate prototypes is important for extending the DDB’s services to the end user. A graphical user interface has been developed as a separate tool that interacts with the DDB via the tool interface. This end user interface extends to the user those functions defined in chapter IV of this thesis. The end user interface is discussed briefly in the next section.

2. End User Interface

Due to the scope of the DDB’s requirements, we need to separate the DDB’s functionality from the user interface functionality. For this reason the end user interface requirements of the DDB were removed and developed separately from the functions provided by the DDB. A graphical user interface developed at the Naval Postgraduate School allows the designer to take full advantage of the functions provided by the DDB [Ref. 14]. The user interface runs under the control of the tool interface. An example of the screens which a user will see when he requests access to prototypes stored in the DDB is illustrated in Figures 3 through 6 . These figures illustrate the sequence of panels a designer will see/use when generating the following DDB commands:

- List the names of the initial decomposition of prototype operators stored in the DDB and search for a component contained inside of the composite

- component “user_interface”
- View a component’s PSDL Source
- Select and Edit a prototype’s attributes

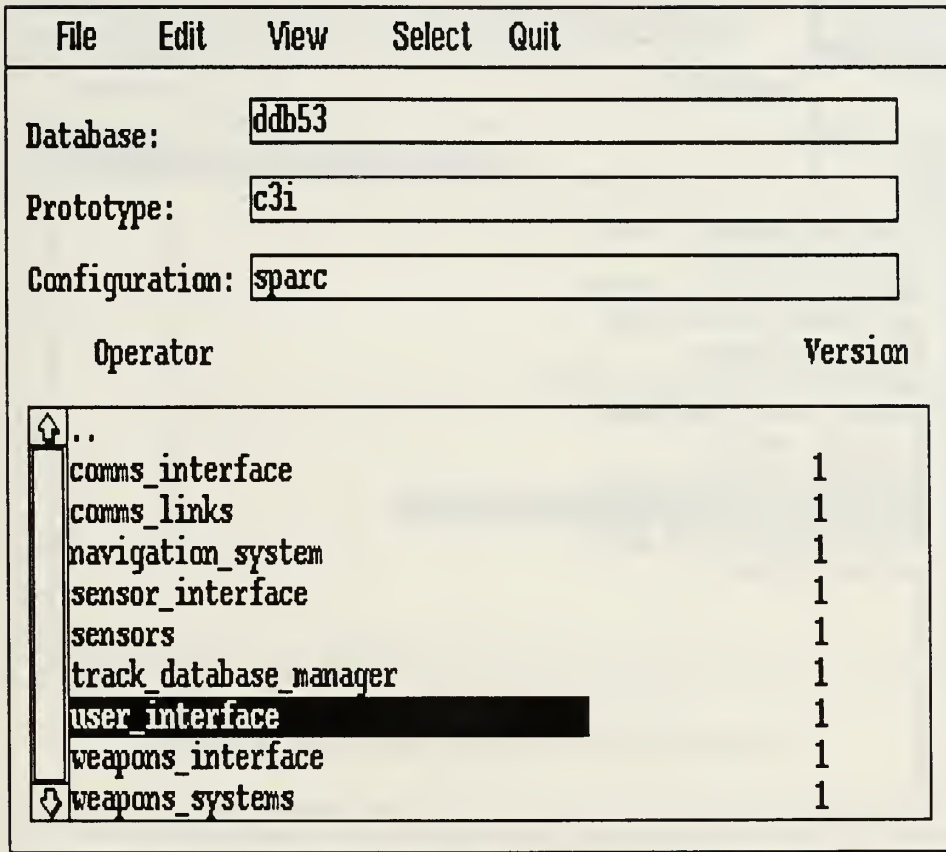

Figure 3. DDB User Interface (Search for Component)

The user moves the selection bar to the desired versioned component (Operator). After the operator (user_interface) is highlighted, double click on that component to see the decomposition of that operator. The resulting view of the decomposition of the user_interface operator is shown in Figure 4.

After the PSDL operator **message_editor** is highlighted (single clicking on that operator) the designer selects the pull-down menu option File and moves the selection bar

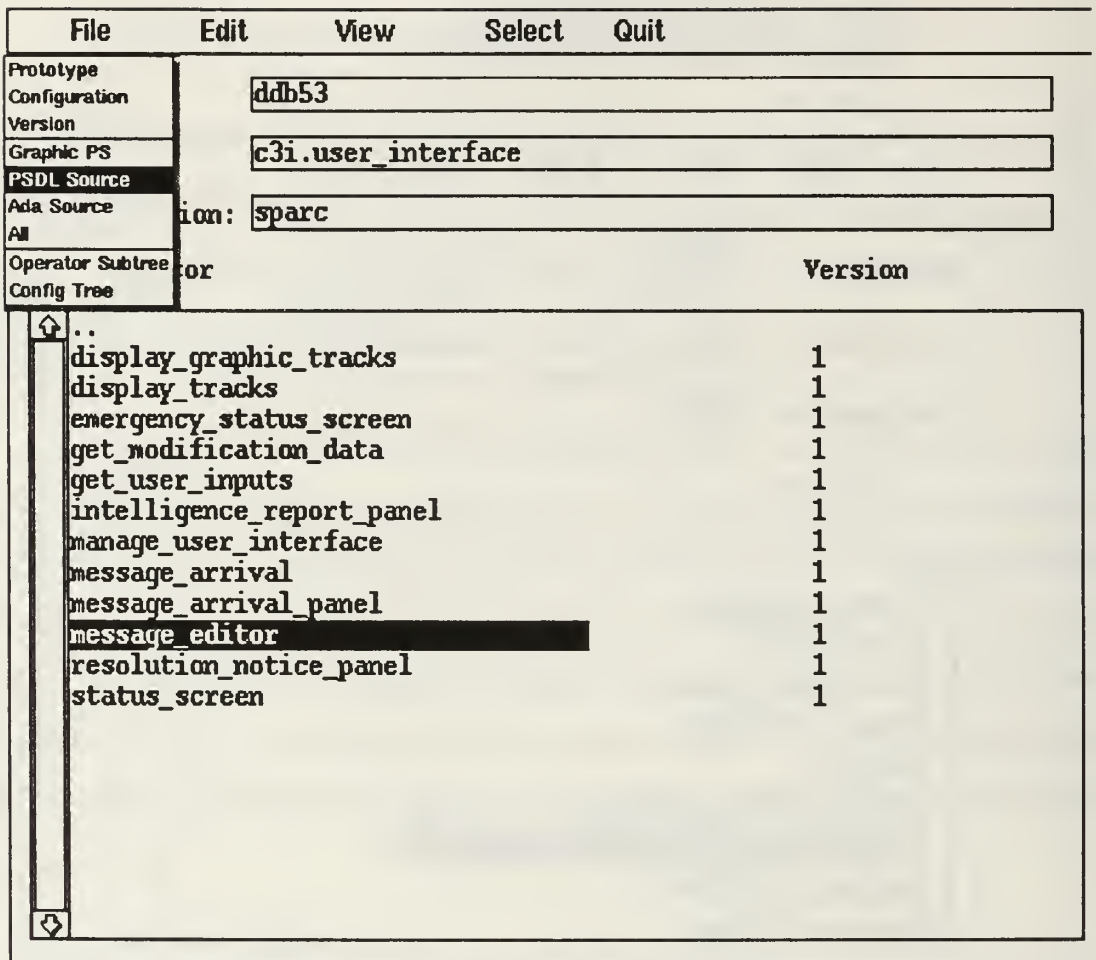

Figure 4. DDB User Interface (View PSDL Source)

to PSDL Source. When that option is activated the user is able to view the contents of the PSDL Source for the message_editor (not shown).

In Figure 5 the user highlights the prototype c3i and selects edit prototype. The results of this action (Figure 6) present the user with an edit screen which allows him to edit various data fields of the prototype. The composition of prototypes and other classes implemented in the DDB will be explained in Chapter IV.

This method of developing the user interface (DDB->tool interface->user interface) enhances modularity and provides flexibility to the overall CAPS system. Consequently,

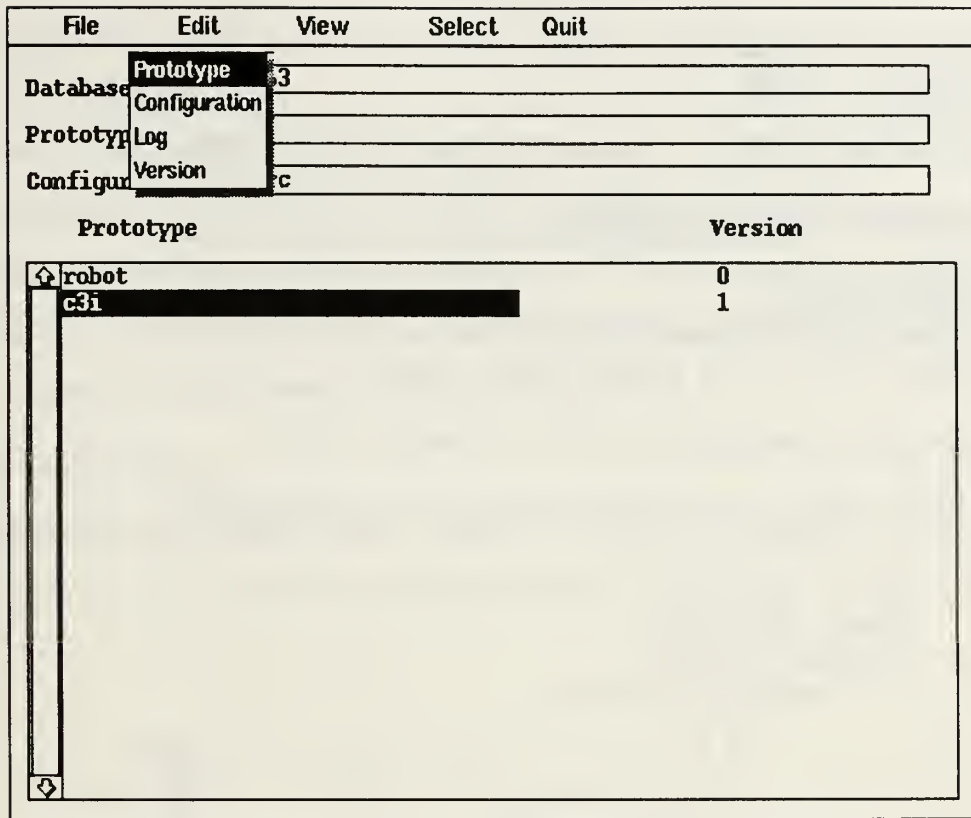

Figure 5. DDB User Interface (Edit Prototype))

whatever form the tool interface and other tools assume in the future, the functions of the DDB shall require little modification. Designing the DDB in this manner permits porting the CAPS system to different graphical user interfaces existing on a wide variety of system platforms.

The above examples represent a small portion of the capabilities of this engineering database. These functions are further defined later in this thesis. Hereafter in this chapter the term “user” will be used generically to refer to the tool interface and/or prototype designer (end user).

C. ENVIRONMENTAL MODEL

The DDB statement of purpose, event list, and context diagram are contained in Appendix A. A summary of the model is presented in the remainder of this chapter.

1. Working Environment

Prototypes are developed in a system work area for CAPS development specified by a case sensitive Unix environment variable (\$PROTOTYPE) defined by the user . The value of this variable should be the path name of a unique Unix directory. The DDB reads this system variable to ascertain where to output prototype components. Components are

immutable snapshots of prototype development efforts. Components may be composite - in which case they contain other components, or they may be atomic - in which case they do not have a decomposition. Atomic components may be transformed to composite components in future decompositions. Once a prototype is stored into the DDB, the database copy may not be altered. To modify a prototype, a copy of the prototype must be checked out of the DDB and put into the user's local area. The user then modifies the working copy. When this copy is significantly altered and certified as an updated version it is checked back into the DDB as a new version of the prototype. This process is called threading components [Ref. 11].

2. Version Structure

Each component represents a PSDL operator or type. Every component in the DDB has its own unique thread. This concept is illustrated in Figure 7.

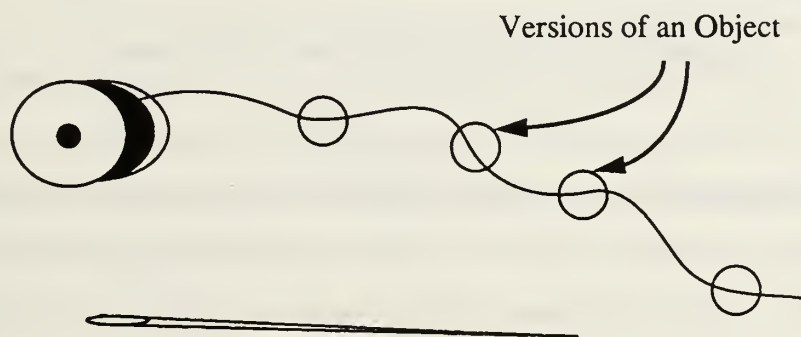

Figure 7. Threaded Components

Versions of a component are ordered by a thread. Each component in the database may reference several types of files generated by various CAPS tools. Figure 8 shows the potential set of files generated for a single component in the DDB.

Inserting a component in a thread and storing it into the database can be modeled as creating a node in a multi-level acyclic graph. In the fully developed model, threads may split at

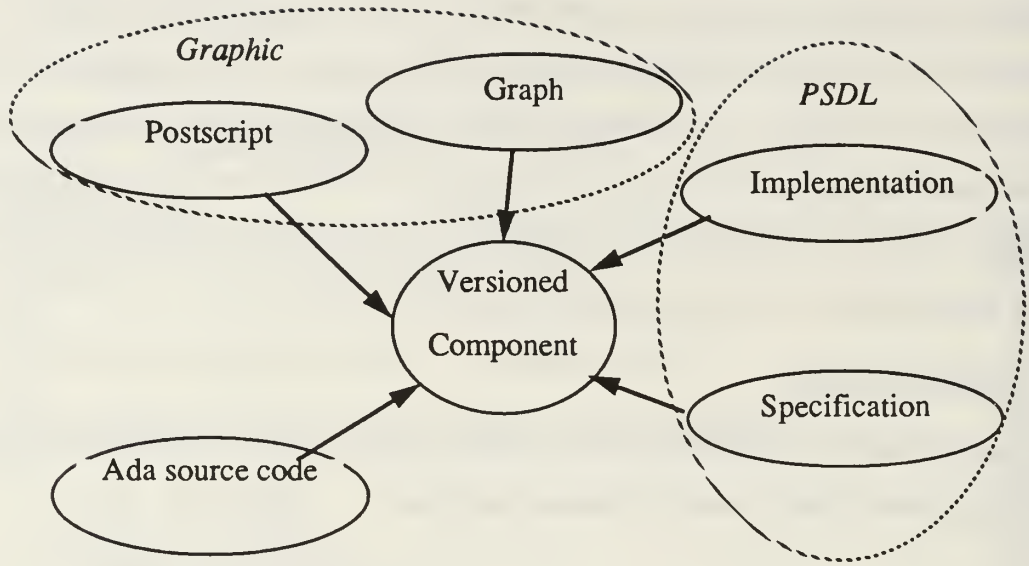

Figure 8. CAPS Files in Versioned Component

any point into variations [Ref 11]. In the current implementation, there is no provision for a segmented join of separate variations, although the groundwork has been laid in the design of object oriented structures which supports a transition to the full model. Decomposing components is an essential requirement for modeling the problem domain. This decomposition produces a multi-level k-ary hierarchy that must be navigated effectively to view and modify any version object upon demand. For this reason “walking the graph” [Ref. 17] is essential.

Three of the primary entities identified for the DDB - a **prototype**, a **configuration**, and a **versioned component** will be discussed in the next section.

Taken as a whole, CAPS, PSDL, and the DDB provides the software developer the ability to store, retrieve, and manipulate an unlimited number of prototypes and components. Working jointly with the other tools in the CAPS system, the DDB provides a capability never before available in computer aided prototyping. This enables the

development of large, real time, or embedded application prototypes more quickly and efficiently.

D. BEHAVIORAL MODEL

Just as a motion picture is a collection of still pictures, a prototype is a collection of versioned components. Our ability to understand a movie is directly related to how well we can grasp the relationship and flow from one frame to the next. Taken together as a movie, these frames can convey something of power and beauty. Developing a software prototype is analogous to understanding a movie. With the right grasp of the tools available in computer aided prototyping, we can form truly productive prototypes. It is the relationship of one version to the next that conveys the direction of future development. As this transformation is captured and tools such as this DDB become fully mature, changes in one component that are dependent on another will be largely realized by automated transformations internal to the tool. These DDB consistency checks ensure that all components interact through their relationship in a database hierarchy. It is for this reason that cataloging and indexing individual CAPS components is essential. This is referred to as Evolution Management. [Ref 11]

The basic prototype functions are illustrated in Figure 9.

The DDB supports the viewing, storing, and retrieving of prototype components in a central design repository. Since prototypes are usually multi-level decomposed subtrees, the DDB provides a mechanism for viewing the complete hierarchy of a prototype components. The DDB stores components required by the other CAPS tools indefinitely. The DDB has no destructive capabilities on the attributes displayed in Figure 8. Once prototypes are posted to the DDB they will never be removed - although a capability to migrate prototypes to archival storage such as tape is planned. The DDB supports the concept of configuration control on a desired slice of the entire prototype history. The DDB does not store repetitive copies of individual components which do not have different versions.

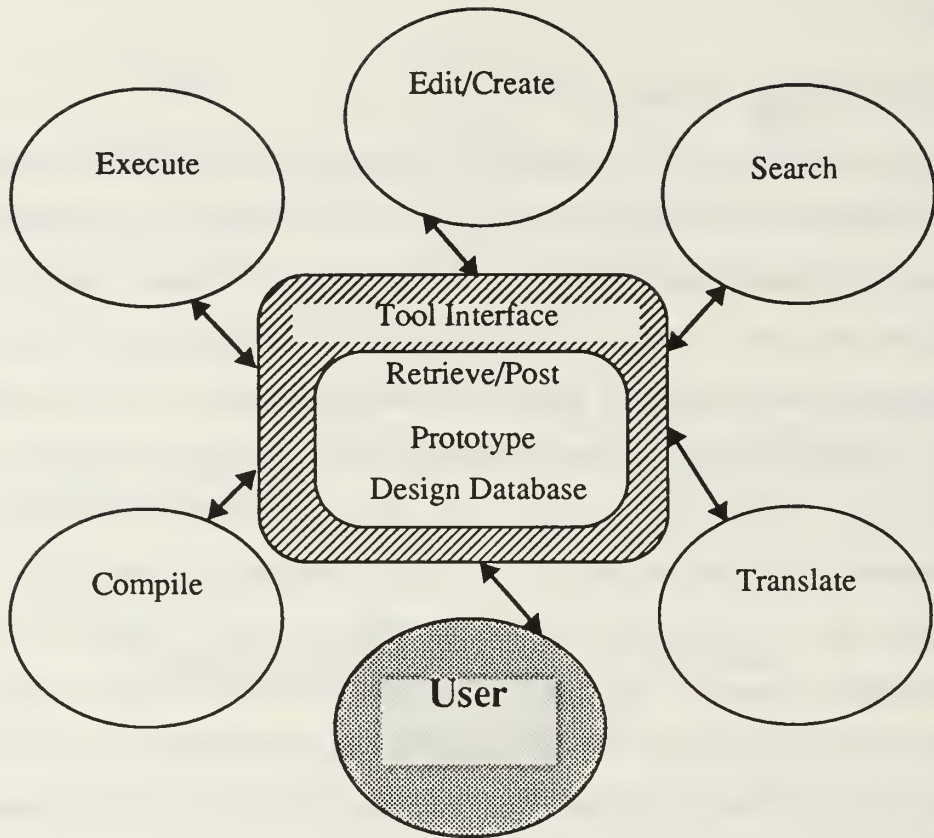

Figure 9. Basic DDB/CAPS Functions

1. Design Constraints

The DDB processes commands from the tool interface. The manner in which data is passed between the tool interface, the DDB, and the end user interface is illustrated in Figure 10. The tool interface controls the user interface. The DDB communicates indirectly with the end user through the user interface's handling of output from the main function calls to the DDB. Since the functionality of the DDB is separated from the user, security is enhanced and there is less chance for error.

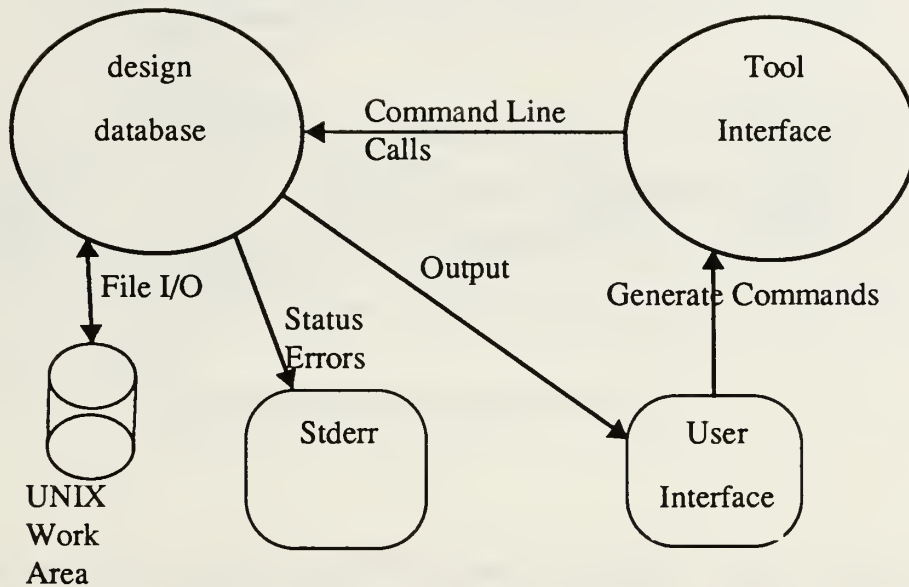

Figure 10. Tool/User Interface

2. Requirements

The user interface captures the standard output and displays it to the user in a window. The data flow diagram of the DDB is shown in Figure 11. The DDB first parses the command line to verify that the command contains a legal function tag and the appropriate number of arguments. A listing of the valid commands to the DDB is contained in Appendix B. After parsing the command, the DDB prepares the ONTOS DBMS for storage and/or retrieval by issuing specific ONTOS DBMS calls. Next the DDB reformulates the command and initiates the sequence of functions required to perform the transaction. At this point, the DDB will perform a query of persistent objects stored in the database or will create and input components designated to be checked into the database. The remaining step displays confirmation and/or displays the data to standard output (stdout).

The end user can then choose to work with one of the other tools in the CAPS system for an indefinite period of time. When the designer/manager is ready to check a revision of the prototype back into the DDB he will provide the tool interface a prototype name and have the tool interface command the DDB to search

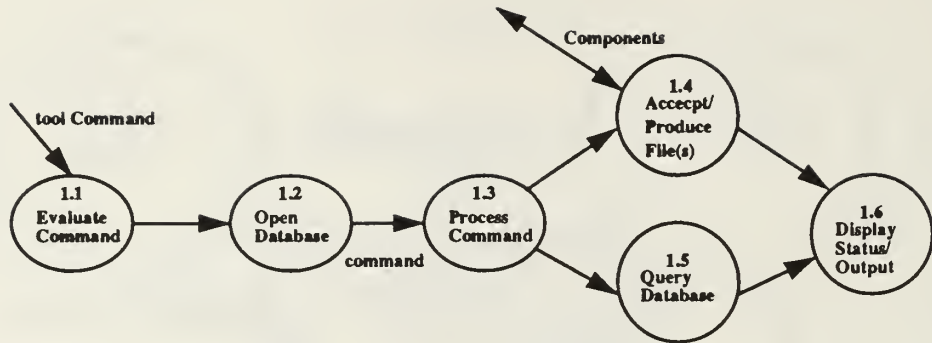

Figure 11. Design Database Data Flow

the working directory defined by \$PROTOTYPE to check modified or newly created components into the database as a new version of the prototype.

The capabilities provided to the user will at a minimum contain the following high level operations:

- Insert new prototypes into the DDB
- View existing prototypes available in the DDB
- View/Update prototype attributes
- Insert new configurations into the DDB
- View existing configurations available in the DDB
- View/Update configuration attributes
- Insert new components into the design DDB
- View versioned components available in the DDB
- Retrieve selected versions of components from the DDB
- Prevent others from versioning components which are currently evolving
- Update previous versions spawning alternate thread histories
- View/Update component descriptions in the DDB

In addition to the above capabilities, the DDB will allow the tool interface to:

- Override component locking mechanisms
- View component lock status

- View a worker which currently has a component locked
- List decomposition of operator/type components and their descendants
- Attach any component to a configuration
- Navigate the hierarchy from any component directly or through a configuration.

More generic database management capabilities are provided by the ONTOS object oriented database. These DBMS capabilities are considered vital to the successful implementation of any database management system. For further information pertaining to these and other ONTOS issues the reader is referred to Chapter II and the ONTOS (version 2.01 beta) users' manual.

IV. ARCHITECTURAL DESIGN

Much of the analysis and research in this area dictates an object oriented approach for classifying the schema and functions of a prototyping storage and retrieval system. To version components which carry information relating to specifications of a software prototype the DDB is modeled in terms of its major classes TEXT_OBJECT, COMPONENT, VERSIONED_OBJECT, THREAD, CONFIGURATION, and PROTOTYPE. In this chapter we define these classes, their behavior and attributes, and the operations they perform.

A. GOALS

The process of developing this application utilizes the object-oriented Programming concepts of specification, implementation, and refinement [Ref. 18:p. 5]. First we collect the requirements in terms of user needs. The result of this phase is documented in Chapter III. The next step is to develop a conceptual solution to the requirements. We then convert these conceptual ideas into concrete classes and operations. This is accomplished by first converting the entity-relationship (ER) diagram to a functional specification.

From the functional specification we determined that a command line interface would best satisfy the requirement for separating the functionality of the tool from other CAPS tools and from the end user. The command line interface divides the functionality into three distinct classes - functions dealing with prototype level operations, those concerned with configurations, and those dealing with versioned component objects. The complete command line interface is contained in Appendix B.

Now we develop an informal solution followed by a formal solution to the stated design requirements.

B. DESIGN DATABASE

1. Informal Solution

The DDB must contain a class structure and methods which support the storage, retrieval, and management of CAPS prototypes. Next we integrate the ONTOS object oriented Database Management System with locally engineered classes and methods designed to support the informal solution and stated requirements. This equates to designing a database schema. Choosing this approach carries several distinct advantages:

- Saves money because the DDB can be developed in less time
- The ONTOS system provides an extensive developer's library
- Enhances Security
- Network capabilities are built in
- Encourages the use of off the shelf generic software programs
- Incorporates enhanced documentation on data structures provided by ONTOS
- Ensures modularity

These and other advantages are discussed in Chapter II.

2. Entities and Their Relationships

The set of files reflected in Figure 8 become the primary attributes of a versioned component in the database. Other attributes required to effectively scope and manage these components and the unique capabilities supported by versioning are contained in the ER diagram shown in Figure 12.

Figure13 shows the lower level entities required to support the data structure of a versioned component. The entities THREAD, COMPONENT, and TEXT_OBJECT reflect the core elements stored as objects in the ONTOS database.

3. Pre-defined ONTOS Classes

The main ONTOS classes used in this DDB application are:

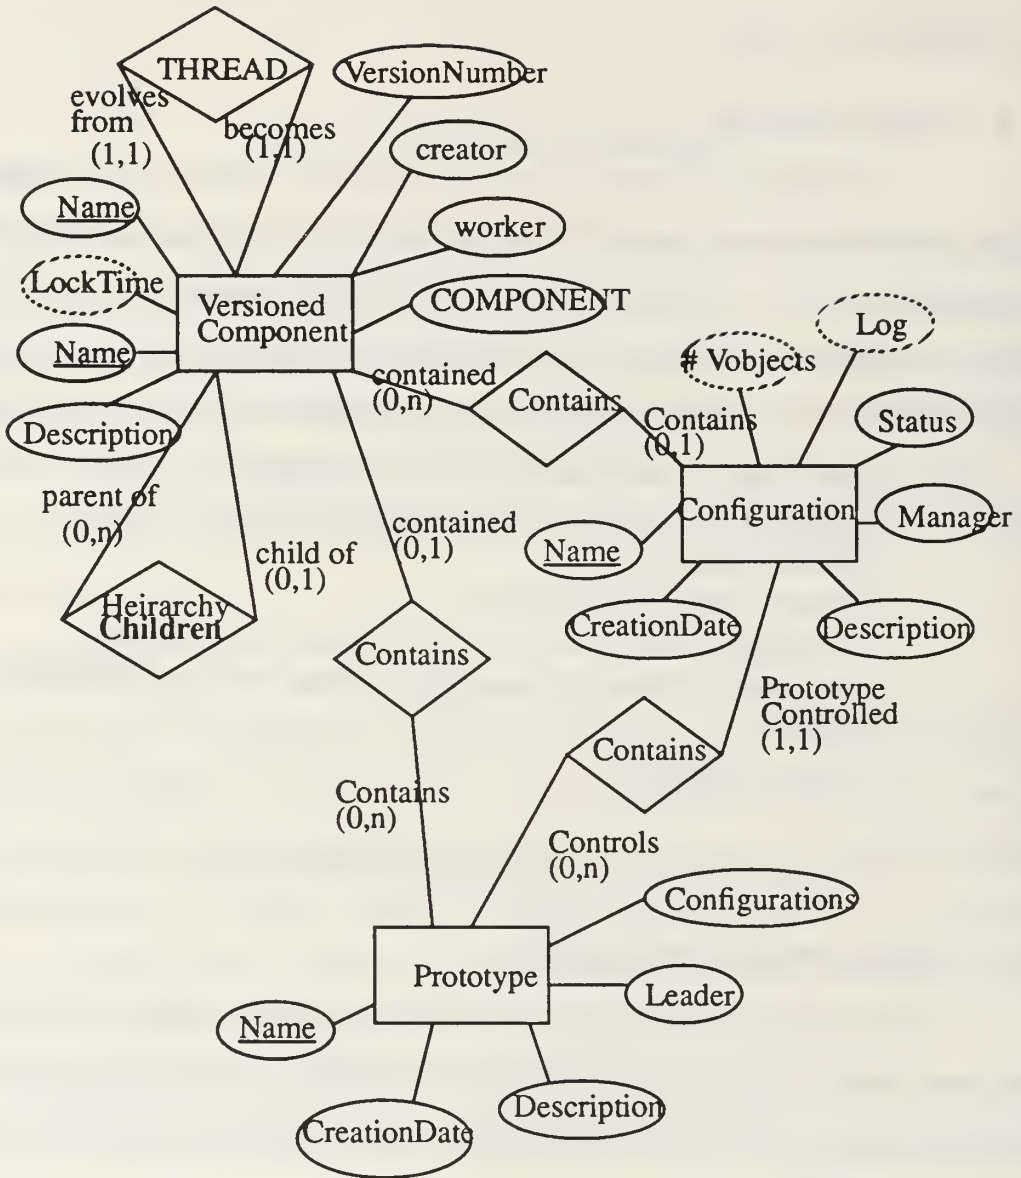

Figure 12. Design Database Entity Relationship Diagram

a. Object

Object is the class used to create persistent objects in the DBMS. All classes requiring persistence must inherit from Object. Persistent objects exist for longer than the immediate I/O session. An object is persistent if you can store it in the database and retrieve it at a later time. If an object is persistent it must have a unique id. This identification

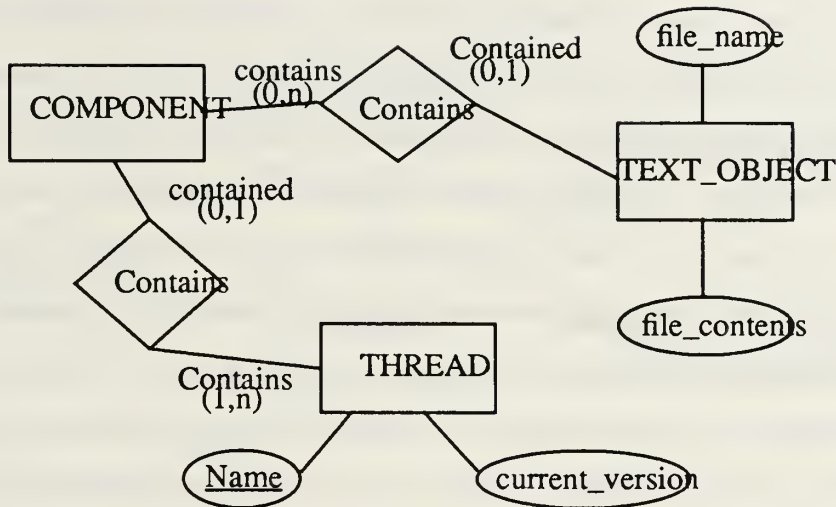

Figure 13. Design Database Entity Relationship Diagram

number may be explicitly assigned by the DDB application or defaulted to a unique id key field generated by methods provided by this ONTOS class. This allows us to store several different components in the database with the appearance of each component having the same name.

b. List

Lists belong to a container class which can store other objects of any type. As a basic data structure, its sister class List_Iterator is used to iterate from one instance of an object to the next.

c. Dictionary

Working on an indexed set of objects contained within it, Dictionary is also a container class. It differs from List in its implementation and in its available methods for directly accessing any item contained within it based on key values.

4. Design Database Classes

The DDB classes and methods work to provide the user the functionality of a library. You can check components in or out. However, unlike a library, when you check

components out of the database for updating, a “copy” of the components is put into your private work area. These components are then flagged inside the DDB as being “locked”. This lock prevents other designers from checking out the same components for updating. The original component remains in the database and can never be altered. It is an immutable copy of the designer’s prototyping efforts at the time it was checked into the DDB. Other workers who attempt to check out the same versioned components may “view” the prototype, but may not modify or evolve the prototype into a newer version. The designer unlocks the prototype when it is checked back into the database. If changes were made to a component then that component will version. If no changes were made then versioning will not be necessary and will not occur. In either case, when a prototype is checked back into the DDB, the locks on components in that prototype are removed.

A diagram of the class hierarchy for the persistent objects in the DDB is included as Figure 14. A class is a high level abstraction that represents something in the real world. All classes developed to support this model are further elaborated with a class description, behavior, attributes, and operations in the rest of this section:

Persistent DDB Classes

Class COMPONENT

COMPONENT is an abstract class in the DDB. It is the core element in the DDB and represents a composite or atomic PSDL operator/type. As reflected in the ER diagram contained in Figure 10, a component contains a variable number of TEXT_OBJECTS.

COMPONENT, like all persistent classes, is a descendant of the ONTOS class Object. If a class intends to store persistent objects in the ONTOS database then the class must inherit from the Object class.

A diagram of these dependencies is shown in Figure 14.

Behavior:

COMPONENT is an abstract container class for TEXT_OBJECTS. It is important to note the distinction between atomic and composite components in the DDB. Atomic objects differ from composite objects in the following way: composite objects

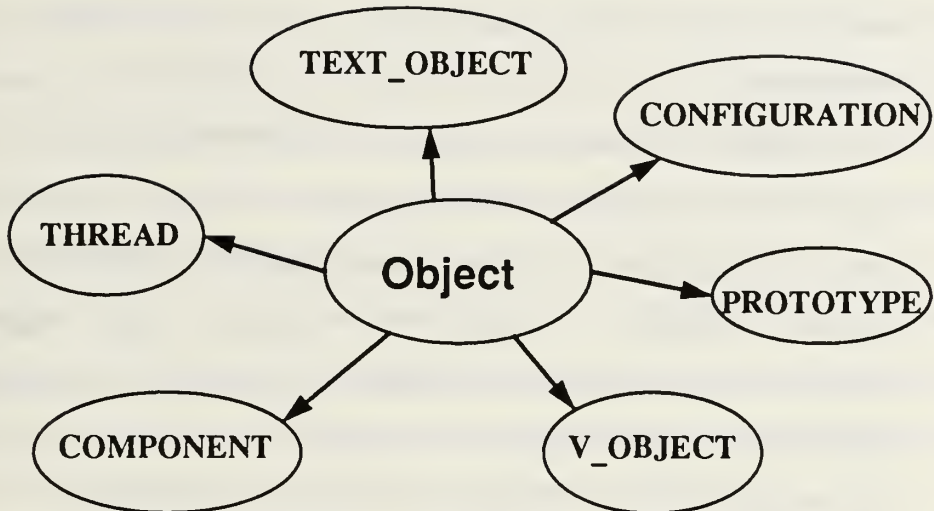

Figure 14. Design Database Descendants of Class Object

decompose into other composite and/or atomic objects, but an atomic object has no further decompositions. In the multi-way tree utilized by this application, atomic objects have no children.

Set of Attributes:

`text_object_list` -> contains the list of `text_objects` in the component. May contain between zero and five of the following files:

Postscript: A file containing Postscript Description Language required by the graphic editor.

Graph: A file containing shapes and geometric point information required by the graphic editor.

Implementation: A file containing either Ada source code or a PSDL decomposition. This file is used by the syntax directed editor, the dynamic scheduler, and the translator.

Specification: A file containing Prototype Specification Description Language (PSDL). This file is used by the syntax directed editor, the software base, the dynamic scheduler, and translator.

Source: ADA Code - a special file containing the source code for the component and/or prototype.

Operations:

COMPONENT -> creates an instance of the COMPONENT class.

getDirectType -> returns an ONTOS Type¹.

GetComponentNames -> returns the names of the TEXT_OBJECTS.

GetComponentSource -> restores the Postscript, graph, implementation, specification, and source file attributes of a versioned component to the appropriate files in the designer's work area.

addTextObject -> adds a TEXT_OBJECT to the COMPONENT.

getPSfile -> restores the Postscript file attribute of a versioned component to the appropriate files in the designer's work area.

getGRAPHfile -> restores the graph file attribute of a versioned component to the appropriate files in the designer's work area.

getSPECfile -> restores the graph file attribute of a versioned component to the appropriate file in the designer's work area.

getIMPfile -> restores the graph file attribute of a versioned component to the appropriate file in the designer's work area.

getSOURCEfile -> restores the graph file attribute of a versioned component to the appropriate file in the designer's work area.

Class CONFIGURATION

When a large prototype is developed and evolved from one version to another, the user may wish to selectively group different versions of the component and its graph subtree into more manageable sets. CONFIGURATION is an abstract class which allows the designer to more effectively deal with selected subsets of components. Remembering that the database will eventually consist of several versions of a prototype and its

1. Refer to Chapter II Section C for definition of ONTOS Type

decomposed components, the user may decide to set up a configuration to reflect version number 1 (CONFIG1) and a newer configuration to reflect those components contained in version number 2 (CONFIG2). Working with configurations, the user may decide that the earlier configuration needs further refinement or that the older configuration is more suited to his application development needs. The DDB will allow the prototype developer to check out the older configuration and retrieve all components contained in that configuration with one single command. When the DDB is fully matured, that configuration will be checked back into the database as version 1.1 - spinning off a new thread from the base thread. This concept of a variation is not implemented in this version of the DDB, but will be developed in the next generation of the tool.

Behavior:

CONFIGURATIONS are entered into the database with commands given in Appendix B. A versioned component is then attached to the configuration as that configuration's default versioned object. With this hook into the prototype tree structure, configurations allow the designer to navigate the prototype hierarchy - to store and/or retrieve versioned components quickly and efficiently to different work areas.

Set of Attributes:

config_status -> reflects the current status of design work. Possible values are 'A' - active; 'T' - archive to tape.

config_manager -> shows who is managing the configuration.

ConfCreationDate -> time/date that the configuration was created.

conf_num_vobjects -> derived field containing the number of versioned components in the configuration.

config_log_entry -> contains a running, non-erasable log journal reflecting all changes to the configuration.

config_description -> A modifiable attribute which contains a generic description of the configuration.

theVersioned_Object -> the default versioned component which serves as this configuration's entry point to the prototype hierarchical data structure. There is only one default versioned component per configuration. This is attached to a configuration after the configuration is inserted into the DDB.

Operations:

CONFIGURATION -> creates an instance of the CONFIGURATION class.

getDirectType -> returns an ONTOS Type.

Destroy -> cleans up the heap.

getConfigName -> displays the configuration name to stdout.

name -> returns the configuration name.

getConfigStatus -> displays the configuration status to stdout.

getConfigManager -> displays the configuration manager to stdout.

getConfigLog -> displays the configuration Log to stdout.

getConfigDescription -> displays the configuration description to stdout.

dumpConfigSummary -> displays the date created, manager, default versioned component, and description to stdout.

listConfigOperators -> lists the entire configuration subtree (all operators from default versioned component).

updateConfigManager -> updates the manager attribute.

updateConfigName -> updates the name attribute.

updateConfigStatus -> updates the status attribute.

addtoConfigLog-> appends entry to the log attribute.

updateConfigDescription -> updates the configuration description.

Class PROTOTYPE

PROTOTYPE is the highest level abstract class. A prototype represents all of the information associated with one prototyping project.

Behavior:

PROTOTYPES are entered into the DDB with commands reflected in Appendix B. PROTOTYPE is a container class which maintains references to CONFIGURATIONS and versioned components (V_OBJECTS). This ability to logically group several configurations and/or components into one prototype allows the designer to more easily manage a variable number of projects at any one time.

Set of Attributes:

protleader -> the name of the prototyping project leader.

protDictIndex -> Required by ONTOS for Dictionary maintenance.

protCreationDate -> The time/date that the prototype was created.

protDescription -> A reference to a TEXT_OBJECT containing a text description of the prototype.

prot_configuration_list -> A reference to a list of configurations associated with a prototype.

prot_default_configuration -> A reference to the last configuration inserted into the prototype.

Operations:

PROTOTYPE -> creates an instance of the PROTOTYPE class.

getDirectType -> returns an ONTOS Type.

Destroy -> cleans up the heap.

getName -> returns the PROTOTYPE object name.

getConfigName -> returns default configuration object name.

getPrototypeName -> displays prototype name to stdout.

getPrototypeLeader -> displays prototype leader to stdout.

getPrototypeDescription -> displays prototype description to stdout.

changePrototypeName -> substitutes new name for existing name.

changePrototypeLeader -> substitutes new leader for existing leader.

updatePrototypeDescription -> substitutes new description for current description.

dumpPrototypeSummary -> displays the date created, leader, default configuration name, and description to stdout.

addConfiguration -> adds configuration to prototype configuration list.

listConfigurations -> lists configurations to stdout.

setProtCreationDate -> sets the prototype creation date to system time.

getProtCreationDate -> returns a time/date of prototype creation.

getDefaultConfigName -> displays the default configuration name to stdout.

getConfiguration -> returns the configuration requested.

getDefaultConfiguration -> returns the default configuration.

getVobject -> returns the most current versioned component matching the prototype name.

Class TEXT_OBJECT

TEXT_OBJECT contains a file name and its associated text.

Behavior :

Accept the file name, construct an object in the ONTOS database to store the name and file contents, and read the file contents into the persistent object.

Set of Attributes:

the_file_name -> name of the tool file.

the_text -> contents of the text file.

Operations:

TEXT_OBJECT -> creates an instance of the TEXT_OBJECT class.

getDirectType -> returns an ONTOS Type.

Destroy -> cleans up the heap.

append -> reads the contents of the file into the ONTOS object.

text -> sends a stream to output file.

rebuildTextFile -> rebuilds the text file in the user's work area and returns completion status.

displayFileName -> displays the file name to stdout.

getFileName -> return the file name.

text -> returns the object's text.

resetTheText -> resets the text attribute.

Class **THREAD**

THREAD is a high level abstract class which contains one or more versions of the same component. Additional components added to a thread have a version number determined by incrementing the highest version number of a component in the thread by one.

Behavior :

A thread is created for every new component entered into the database. Most methods check for the existence of a **THREAD** prior to executing a requested operation.

Set of Attributes:

current_version -> version number of the most recent version on the thread.

the_list -> an ONTOS reference to a List containing different versions of a component.

Operations:

THREAD -> creates an instance of the **THREAD** class.

getDirectType -> returns an ONTOS Type.

Destroy -> cleans up the heap.

getCurrentVersionNum -> returns the integer current version.

current -> returns the versioned component (**V_OBJECT**) having the same version number as the current version attribute of the thread.

version -> returns the versioned component (**V_OBJECT**) having the version number supplied by the calling method.

add_object -> adds a new versioned component (**V_OBJECT**) to the thread.

displayThreadVersions -> display the version number of every versioned component (V_OBJECT) in the thread.

displayThreadContents -> displays the version number and the description of every versioned component (V_OBJECT) in the thread.

Class V_OBJECT

V_OBJECT is an abstract persistent class. It represents an immutable snapshot in time of an operator/type that was checked into the database as part of a prototype design.

Behavior:

V_OBJECTS are entered into the DDB with commands reflected in Appendix B. Only the root V_OBJECT must be entered by the user (tool interface). The TREE class then scans the directory for other operators which are descendants of that operator and constructs a tree structure for comparison to the contents of the database.

Set of Attributes:

theVersionNumber -> the component's version number.

creationDate -> the date the component was created.

lockTime -> the date the component was created. Evaluated as the system's epoch time if not locked. Epoch time means no lock is set and lockTime equals zero.

node_name -> short node name. No ancestor information. The long name is contained in the THREAD class.

creator -> name of the end user who created the component.

worker -> if the component is locked, then this attribute contains the name of the worker who checked it out.

visited -> a boolean used to navigate the tree structure.

last_op_checkin -> a boolean used to prevent duplicate checkin operations.

theDescriptionPtr -> TEXT_OBJECT containing the description for this versioned component.

theThreadPtr -> pointer to the THREAD this versioned component is contained in.

theCOMPONENTPtr -> points to the component which contains the text object's for this versioned object.

theChildPtr -> points to a list of Children.

theParentPtr -> points to the most current parent.

Operations:

V_OBJECT -> creates an instance of the V_OBJECT class.

getDirectType -> returns an ONTOS Type.

Destroy -> cleans up the heap.

connect_vobject_to_thread -> attaches a versioned component to a thread.

setParent -> set's versioned components Parent.

setNodeName -> pulls the short node name from the thread name.

getNodeName -> returns the short node name.

getVobjName -> displays the component name.

getName -> returns the component name.

resetVisitedFlag -> used to navigate the tree.

setVisitedFlag -> used to navigate tree.

getVisitedFlag -> TRUE if visited, FALSE otherwise.

getVObjComponentsName -> display the names of the text objects associated with this versioned component.

displayVersionNumber -> displays the component's version number to stdout.

getVersionNumber -> return the component's version number.

dumpVobjSummary -> displays the date created, creator, worker (or None if unlocked), lockTime (or NONE if unlocked), and description to stdout.

setCreationDate -> The time/date that the component was created

getCreationDate -> returns the time/date the component was created.

setLock -> set's the lockTime immediately following checkout.

getWorker -> return the worker who has the component locked.

getCreator -> return the end user who created the component into the DDB.

setWorker -> set the worker to the \$USER environment variable.

resetLastOpTrue -> if last operation was a checkin, then set the last operation checkin attribute to TRUE. prevents duplicate checkins.

resetLastOpFalse -> on a checkout, reset the last operation checkin to FALSE.

get_last_operation -> returns TRUE if last operation was a checkin.

releaseLock -> resets lock and returns completion status.

getLockTime -> returns the lockTime of the component.

getDescription -> displays the description to stdout.

listChildren -> displays a list of children of this versioned component to stdout.

longlistOperatorNames -> displays a long list of all operators/types in the subtree of this versioned component.

listOperatorNames -> displays a list of all operators/types in the subtree of this versioned component.

updateDescription -> updates the description attribute.

addCOMPONENTNode -> adds a component to this versioned object.

deleteChildNode -> deletes a reference from the list theChildPtr.

addChildNode -> adds a reference to the list theChildPtr.

getParent -> returns the parent of this versioned component.

getCOMPONENT -> returns the component of this versioned object.

dumpSubtree -> rebuilds the versioned components in read-only or read-write mode into an end user's \$PROTOTYPE directory.

releaseLockSubtree -> releases the lockTime on all versioned components in this component's subtree.

getChildren -> returns the list of Children of this versioned component.

getChildPtr -> returns TRUE if the cardinality of children of this component is greater than zero.

checkoutCOMPONENTNode -> rebuilds all text objects of the component attribute of this versioned object and returns completion status.

Non Persistent DDB Classes

Class DIRECTORY

A non-persistent class designed to evaluate the status of prototypes being checked into the DDB.

Behavior:

This class has no direct relationship to the end user interface. The directory class searches the \$PROTOTYPE subdirectory of the designer, determines what operators exist that match the prototype name, and develops a linked list of nodes to be inserted into a multi-way tree. The output from this class is passed to the TREENODE class for insertion of nodes into the persistent database.

Set of Attributes:

TREENODE_linked_list -> operator/type nodes contained in the user's PROTOTYPE directory.

Operations:

DIRECTORY -> constructor for building a directory scanner.

read_directory -> Given a root operator, scans the user subdirectory for prototype component matches. Builds a list of all prototype components. Stores the potential component matches in a linked list of operator nodes.

updatetimestamp -> evaluates whether component files in the user work area are newer than the versioned component stored in the ONTOS database. This information is used by the TREENODE class when determining whether to create a new version of the component.

find_treenode -> scans the linked list of operator nodes to build the multilevel k-ary tree of TREENODES. Both operator nodes and TREENODES use the same class structure, except that the operator nodes have no children (subtree) references.

getOperatorList -> required to build the multilevel k-ary tree. Returns the operator list defined by evaluating the users work area with the read_directory operation.

Class QUEUE

QUEUE contains the basic non-persistent queue data structure required to construct the multi-level k-ary hierarchy.

Behavior:

Implements basic queue functions.

Set of Attributes:

None.

Operations:

put -> append an operator TREENODE on the queue.

get -> get an operator TREENODE from the queue.

empty -> test the queue for empty status.

Class slist, slink, slist_iterator, slink_iterator

These classes are non persistent abstract classes providing the generic capabilities of a singly linked list.

Behavior :

these classes contain the basic data structures required for queues and linked lists.

Set of Attributes:

e -> treenode pointer.

next -> link pointer.

ce, last -> slink pointer.

cs -> slist pointer.

Operations:

slist, slink, slist_iterator, slink_iterator -> constructors.

insert -> add TREENODE at head of list.

append -> add TREENODE at tail of list.

get -> return TREENODE.

clear -> remove all links.

empty -> test for empty list.

Class TREE

A non-persistent class designed to build a multi-way tree of operator/types developed by the end user in the \$PROTOTYPE directory.

Behavior:

The TREE class will establish the root operator and build the tree.

Set of Attributes:

tree_name -> assumes the name of the prototype root versioned component.

theTreeRootNode -> TREENODE (root of multi-level k-ary tree).

Operations:

TREE -> constructor for building the root TREENODE.

build_tree -> builds the multi-level tree.

find_treenode -> returns a TREENODE from the input list of Operator nodes returned from DIRECTORY.

Class TREENODE

The most important non-persistent class designed to build a multi-way tree of operator/types developed by the end user in the \$PROTOTYPE directory.

Behavior :

The TREENODE class is used to establish the operator node list, to convert the operator node list to a multi-level tree, and to compare each node in the multi-level tree to versioned components in the database. Component versioning occurs where the TREENODES have newer timestamps than the lockTime on the versioned components.

Set of Attributes:

tree_node_name -> explicit name of node (from root node to level in subtree).

Taken in its entirety, the tree_node_name contains the sequence of ancestor names from the entire prototype name to the given sub-component's node_name.

node_name -> unique name of operator/type without level/ancestor information.

timestamp -> contains the operator/types most recent system time. Each tool updates the file when it creates or updates its product files.

level -> root operator equals 1. Other nodes reflect the level where they reside.

ChildrenList -> linked list of TREENODE descendants of this instance.

ParentNode -> parent TREENODE of this instance.

Operations:

TREENODE -> constructor which reads directory and builds operator list.

updatetimestamp -> reads the directory again for the newest of potential files for each operator/type developed by CAPS tools. Stores the result in timestamp.

getname -> returns the TREENODE name.

insertChildNode -> inserts a TREENODE into the ChildrenList.

getChildren -> returns the linked list of Children TREENODES.

getParentNode -> returns the Parent TREENODE of this instance.

get_asc_time -> returns the 26 character ASCII time from the standard C function ctime.

getlevel -> return the level of this TREENODE. root is level 1, successive levels increment by 1.

get_long_time -> return the timestamp.

list_subtree -> lists each TREENODE from the root to each leaf node.

checkin_subtree -> initiates the recursion for comparing the tree of TREENODES to the hierarchical structure in the ONTOS database.

checkin_node -> does the bulk of the loading into the ONTOS database. Creates new threads and versioned components when the TREENODE timestamp is more

current than the versioned component's lockTime or where no thread with that operator name exists (new operator).

C. TESTING AND EVALUATION

The method used for checking the functionality of the DDB required an exhaustive check of many possible variations of the functions documented in Appendix B. To demonstrate that each of the commands produce the desired output, a unix shell script was generated which tested all of the functions. The complete version of this shell script test is contained in Appendix C.

The output from this sequence of commands, also contained in Appendix C, shows that the testing phase answered two very important questions affirmatively - that this tool could successfully store and retrieve versioned components of prototypes as dictated by the design criteria; and that the software engineering design database could be developed as a stand-alone tool which interacted with other tools through the tool interface.

The results of some commands can not be verified by running that command alone. It is only by running several commands in a series that the effect of one command changing the state of the database can be verified. Consequently, these types of tests were included in the testing phase.

D. MAINTENANCE NOTES

All code generated by the authors in support of this implementation effort is contained in Appendix D.

This code was developed using version 2.0 of the Glockenspiel C++ compiler and the beta version 2.01 of the ONTOS object-oriented Database Management System. ONTOS tools included packages containing extensive capabilities for debugging in the form of the ONTOS graphical database browser (DBrowser).

Special ONTOS header files and the makefiles used during compilation are contained in Appendix E.

V. CONCLUSIONS AND RECOMMENDATIONS

A. SUMMARY

The goal of this thesis research was to design and develop an engineering database which could store, version, and retrieve software prototype components. This database provides concurrent users the command functions to insert prototypes, store and manage configurations, and insert and retrieve components throughout the software engineering life cycle.

The prototype functions allow the designer to store and retrieve management information concerning any of several potential prototype designs.

The configuration functions allow the designer to more easily navigate the various versions of a software prototype. It provides him a “hook” for navigating the hierarchy from any specified component. With additional features such as grouping by configuration and logging, configurations provide powerful features and a sound design for the development of evolution management into the engineering database model.

The versioned component functions give the designer the flexibility to checkout for modification or viewing specific prototype components; to expand, modify, and decompose these components with other tools in the CAPS system; and to check selected portions of those components back into the database at any time[Ref. 19].

B. RECOMMENDATIONS FOR FUTURE WORK

1. Variations

Variations will allow users to check out older versions of components and/or groups of components and evolve them to newer versions. When the updates are completed components will version correctly - splitting, updating, and rejoining threads where appropriate. Work must be done on other tools in the CAPS system to make them accept as input and produce as output components which contain version information. This will

provide the DDB with the necessary information for re-attaching components to the hierarchical structure at the correct location.

2. Security

This implementation of the engineering database does not address the issue of security other than the concurrency control mechanisms. This thesis makes no effort to distinguish between different levels of access or authorization for access to objects and their attributes. This is a subject that requires additional research and development.

3. Evolution Management

This program must be enhanced to incorporate the “uses” and “derives” properties [Ref. 11]. The database will then be capable of automatically flagging the effects that changing one component has on other components in the prototype. As components are checked out of the database they must take information with them pertaining to the version checked out. This is required to reattach components to the multi-way tree upon update. These and other evolution attributes will become an important ingredient for providing a fully functional engineering database.

APPENDIX A

ENVIRONMENTAL MODEL

A. STATEMENT OF PURPOSE

The Purpose of the design database is to provide the designer a method of storing and retrieving components generated by the various tools of the COMPUTER AIDED PROTOTYPING SYSTEM (CAPS). This tool shall be flexible enough to expand as other tools are developed. It shall be capable of maintaining older versions of components as new components are developed. It shall allow the user to version new and/or older components with the common interface considerations.

B. EVENT LIST

List prototypes

List current version of prototype

Select current version of prototype

Check out current version of prototype's components for viewing/update

Add new version of prototype's components

List previous versions of prototype

Select previous version of prototype

Check out previous version of prototype's components for viewing/update

List selected prototype attributes (creation date, leader, etc)

Update selected prototype attributes (leader, description, etc)

List composite components (operators/types)

List atomic components (operators/types)

List selected versioned component attributes (date created, description, etc.)

Update selected versioned component attributes (date created, description, etc.)

List configurations

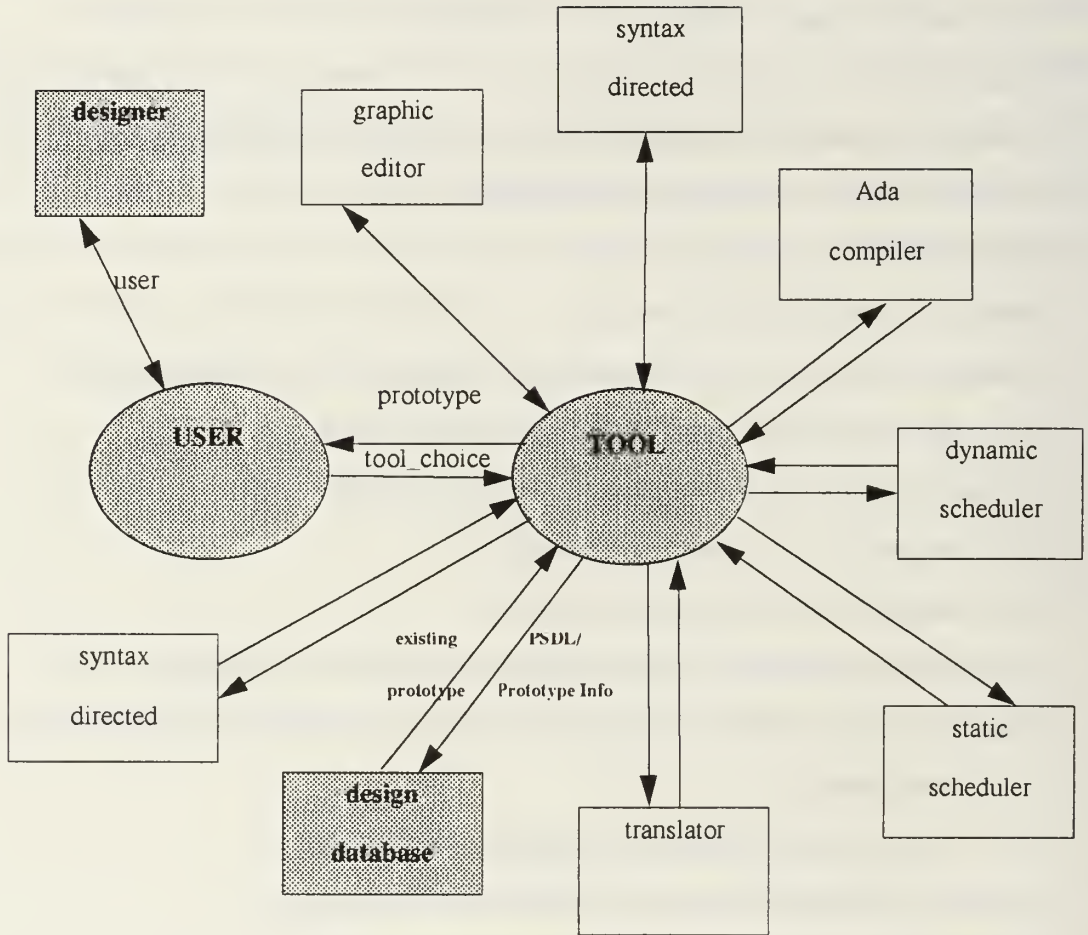

List current default version of configuration in prototype

Select current default version of configuration in prototype

Check out current version of configuration for update

Add new version of configuration's components

C. CONTEXT DIAGRAM

CAPS Interface Data Flow Diagram (partial/modified) [Ref. 3:p. 19]

VGS	Get Source	file	ddb <db> vgs <p> <v> R/W [version]
VDF	Dump Operator Atomic ^h	file	ddb <db> vdf <p> <v> R/W [version]
VDT	Dump Operator and Subtree	file(s)	ddb <db> vdt <p> <v> R/W [version]

- a. <angle brackets> reflect required parameters. [square brackets] denote optional parameters.
b. <db> db=any Ontos Database name. <p> p=any prototype name <c> v=any vobject name
c. Operator name containing explicit path information for determining location (level) in heirarchical data structure
d. Node name containing no reference to location (level) in heirarchical data structure
e. Only Creator may update description

f. file containing description

g. R/W dump file for Read-Only (R) or Write (W). Tool interface must supply either R or W to build files

h. Atomic is considered collection containing .ps .graph .imp.psd1 .spec.psd1 and .a file(s)

APPENDIX C

TESTING AND EVALUATION

A. NOTES ON TESTING AND EVALUATION

For functions which return no visible output, the successful completion is marked by the standard output of:

CAPS Engineering Design Database 1991(c) WP.D.A.L.G

Three Prototypes are inserted into the Engineering Database. These include one Command and Control Application (**c3i**) and two classroom applications (**FishFarm** and **Robot**). The purpose for inserting three applications is to test working with several prototypes. After demonstrating these functions, the remaining functions are run against the more comprehensive prototype created by the CAPS system called **c3i**. This prototype was selected due to it's ability to fully exercise the "graph walking" capabilities of the model.

APPENDIX D

CODE

A. PREPARATION NOTES

This code was written using Glockenspiel C++ version 2.0a.

B. PRINTING NOTES

This code was prepared for printout using the `c++2latex` code generator. This generator parses the ASCII text input files and places latex commands where directed. This makes the code layout more readable and highlights the important data structures and key words within the C++ code. The latex output was then converted to postscript format with the `dvitops` program.

C. MAINTENANCE

This code is maintained at the Naval Postgraduate School Computer Science department.

```

// attach_vobject_to_conf_func
//
// Attaches an instance of the VOBJECT class to a configuration.
//
// update_conf_name_func
//
// Changes the name of a designated configuration.
//
// get_conf_desc_func
//
// Provides a description of the designated configuration.
//
// insert_conf_func
//
// Creates a new configuration and binds it to a particular
// prototype.
//
// update_conf_desc_func
//
// Updates the description text of a designated configuration.
//
// get_conf_manager_func
//
// Provides a configuration manager's name.
//
// update_conf_manager_func
//
// Changes a configuration manager's name.
//
// get_conf_date_func
//
// Provides the creation date of a given configuration.
//
// post_conf_log_func
//
// Adds a timestamped log entry (translated char string)
// to a configuration.
//

```

```

// get_conf_log_func
//
// Provides the text of a configuration log.
//
// dump_conf_operators_func
//
// Write a copy of the operators in a designated configuration
// to disk.
//
// add_conf_operators_func
//
// Add operator from disk to a particular configuration in the
// database.
//
// release_conf_lock_func
//
// Provide a method to release locked operators in a given
// configuration.
//
// long_list_conf_operators_func
//
// List all the children's names and version numbers of a
// given configuration.
//
// list_conf_operators_func
//
// List the immediate children's name and version number of
// a given configuration.
//
// list_conf_default_operator_func
//
// Provides the name and version number of the default VOBJECT
// assigned to the configuration.
//

// Number Defines for Evaluations functions
//
// Description
//
// These #defines are all designed just to pass information back and forth
// between the main program and the modules which evaluate the command line
// for what function to run. There are basically three types of function
// arguments CONFIGURATION arguments - beginning with a 'C', PROTOTYPE
// arguments - beginning with a 'P', and VOBJECT functions - beginning
// with a 'V'. All arguments are exactly 3 characters in length and must
// conform to one of the valid arguments in the designed interface. All
// other arguments will be invalid and return <Invalid Function> to the
// Standard I/O.
//

// In body comment:  
//  
// Here I will create the list to hold those filenames that  
// contain (as a substring) the operator name. This method  
// will also scan those files that do match the pattern input  
// and throw out those with the .ps, .graph, .imp.psdl, .spec.psdl  
// and .a files. What I hope will remain is a list of only those  
// filenames which represent that operator node and it's  
// associated SUBTREE operator nodes. We'll then turn around and  
// process the resulting list into an operator tree structure and  
// compare against the database schema for storage of the  
// .ps, graph, .spec.psdl, .imp.psdl, and .a text objects into  
// the database as collected sets of COMPONENT objects.

// Description -----
//
// list_prot_func
//
// Provide the name of prototypes in the design database.
//
// long_list_prot_func
//
// Provides a list of all prototypes, the default configuration
// assigned to a prototype and the version number of the root
// versioned object.
//
// get_prot_leader_func

```

```

//
// Provides the name of the leader assigned to a prototype.
//
// get_prot_description_func
//
// Provides the description of a given prototype.
//
// dump_prot_summary_func
//
// Provides a summary of the prototype. Include creation date,
// leader, default configuration, and a description.
//
// retrieve_prot_date_func
//
// Provides the creation date.
//
// insert_prot_func
//
// Creates a new prototype in the database.

// Description -----
//
```

```
// Defines the slink, slist, slist_iterator,
// treenode_linkedlist, and treenode_queue classes
```

```
//
// There are no ontos mechanisms in these classes. The primary
// purpose of these classes is to provide the support structures
```

```

// of linked_lists and queues in order to process the CAPS
// PROTOTYPE subdirectory.
//
// As a subdirectory is read, each file is analzed to determine
// whether it is an operator/type. If found to belong to
// an operator which might version, the operator and operator
// information is placed into a multi-way tree parrallelling the
// decomposition of an operator in the CAPS system. The
// TREENODES are then compared against operator structures in
// the Ontos Database in other programs documented elsewhere.
//
// These structures are simple in nature and can be found in
// any good C++ textbook. These particular ezamples came from
// Bjarne Stroustrup's C++ Programming Language textbook (pg 203).
// Please refer to the textbook for further explanation of the
// data structures and how they are manipulated.
//

// V_OBJECT
// V_OBJECT
//
// Constructors - builds a persistent object in the Ontos
// database.
//
// Destroy
//
// Required by Ontos. Every persistent object must have a
// destroy function.
//
// getDirectType
//
// Returns an Ontos Type
//
// connect_vobject_to_thread
//
// Connects a vobject to a thread bearing it's name.
//
// setParent
//
// Used to establish links (Transparent References as Ontos
// calls them) in the Design Database reflecting the
// decomposition of CAPS operators/types.
//
// setNodeName
//
// NodeName is maintained as a separate character string field.
//
// getNodeName
//
// get the shorter NodeName
//
// getVObjName
//
// Displays the versioned object's name to stdout

```

```

//
// getName
//
// returns the character string pointer of the Operator Name
//
// resetVisitedFlag
//
// resets visited to FALSE
//
// setVisitedFlag
//
// sets visited to TRUE
//
// getVisitedFlag
//
// returns the value of visited (Boolean)
//
// getVObjComponentsName

// display the different components in the Operator
//
// displayVersionNumber
//
// Display the version number of the V-OBJECT to stdout
//
// getVersionNumber
//
// return the int versionNumber
//
// dumpVObjSummary
//
// dump predetermined attribute values to the stdout/stderr
//
// setCreationDate
//
// gets the system time and stores it in CreationDate
//
// getCreationDate
//
// Displays the creation date as a 26 character ascii text
// string of the date and time
//
// setLock
//
// sets the lock to the system time
//
// getWorker
//
// returns the character string containing the workers name
//
// getCreator

```

```

//
// returns the character string containing the V_OBJECT
// creators name
//
// setWorker
//
// gets the UNIX UserPtr variable and stores the value of that
// variable into worker
//
// resetLastOpTrue
//
// Tells the system that the last operation on that V_OBJECT
// was a checkin. Prevents duplicate checkins from creating
// new versioned objects on each checkin
//
// resetLastOpFalse
//
// resets the last operation immediately following checkin
//
// get_last_operation
//
// returns a Boolean TRUE if last operation was an add
//
// releaseLock
//
// sets the lockTime back to 0 (epoch time) Sometime in 1969.

// Member Function (in lieu of destructor)//

void V_OBJECT::Destroy(Boolean aborted)

```

```

// Summary -----
//
// This one is semi tricky. Destroy redefined the Destroy
// function inherited from the class CleanupObj. Destroy()
// is used to delete CleanupObj objects and those of all its
// derived classes. In defining any class that is directly
// or indirectly derived from CleanupObj, provide the
// function Destroy(Booleam aborted) in place of a destructor
// if there is any special processing required when the
// object's memory is deallocated.
//
// Parameter
//
// aborted
//
// If Destroy() is called as a result of an abort, aborted
// is set to TRUE; if it is called to delete the object for
// other reasons, aborted is set to False.
//
// Functional Description
//
// CleanupObj in effect provides an audit trail of the
// creation of all stack-based instances of its derived
// classes, so that they can be cleanly deleted in the
// case of an abort during exception handling. Hence
// the Destroy function.

{
    Object::Destroy(aborted);

// Description -----
//
// list_operators_func
//
// Provides a list of operators associated with a
// subtree of a designated versioned_object.
//
// update_vobject_desc_func
//
// Updates the description text of a designated versioned
// object.
//
// get_vobject_desc_func
//
// Provides a description of the designated versioned object.
//
// get_vobject_date_func
//
// Displays the date that the versioned object was created.
//
// get_vobject_versions_func
//
// Checks the thread and displays the different versions.
//
// get_vobject_lock_func
//
// Displays a 26 character text entry reflecting the time
// and date that the versioned object was locked.
//
// get_vobject_version_func
//
// returns the version of the versioned object instance.
//
// dump_vobject_summary_func
//
// displays predetermined attribute fields to stdout/stderr.
//
// get_vobject_psfile_func
//
// rebuilds the CAPS postscript file to the PROTOTYPE
// directory.
//
// get_vobject_graphfile_func
//

```

```

// rebuilds the CAPS graph file to the PROTOTYPE directory.
//
// get_vobject_impfile_func
//
// rebuilds the CAPS implementation file to the PROTOTYPE directory.
//
// get_vobject_specfile_func
//
// rebuilds the CAPS specification file to the PROTOTYPE directory.
//
// get_vobject_sourcefile_func
//
// rebuilds the CAPS source file to the PROTOTYPE directory.
//
// dump_vobject_files_func
//
// rebuilds all of the above files (of one operator) to the
// PROTOTYPE directory.
//
// dump_vobject_tree_func
//
// rebuilds all existing TEXT_OBJECT attributes to the PROTOTYPE
// directory for the entire decomposition of the root operator
// down to the component operators. May be dumped in "read only"
// or "read/write". When dumped, all versioned objects are
// locked for modification by other users.
//
// long_list_children_func
//
// lists the node name and version number of children.
//
// long_list_parents_func
//
// lists the most current parent (and that parents siblings).
//
// long_list_operators_func
//
// lists the node name and version number of a node's children.
//
// release_operator_lock_func
//
// reset the locktime of a versioned operator.
//
// release_subtree_lock_func
//
// reset the locktime of a versioned operator and all children
// of that versioned operator.
//
// add_vobject_and_subtree_func
//
// the reverse of a dumping vobjects. this checks versioned

```

```
// objects back into the database, versioning them if necessary.

APPENDIX E

SETUP FILES

A. ONTOS HEADERS/MAKEFILES PREPARATION NOTES

Only the ReferenceMacros.h ONTOS specific header file is included in this appendix due to its unique nature. It is a file built after the ONTOS system was released and was not included with the standard beta package.

The makefiles are included as an aid for the user in developing ONTOS applications.

B. PRINTING NOTES

This code was prepared for printout using the `c++2latex` code generator. This generator parses the ASCII text input files and places latex commands where directed. This makes the code layout more readable and highlights the important data structures and key words within the C++ code. The latex output was then converted to postscript format with the `dvitops` program.

C. MAINTENANCE

This code is maintained at the Naval Postgraduate School Computer Science department.

```
