#### Abstract

IIere we report on development of a high order finite element code for the solution of the shallow water equations on the massively parallel computer MP1104. We have compared the parallel code to the one available on the Amdahl serial computer. It is suggested that one uses a low order finite element to reap the bencfit of the massive number of processors available.

## 1. Introduction

The shallow water equations are first order nonlinear hyperbolic partial differential equations having many applications in Meteorology and oceanography. These cquations can be used in studies of tides and surface water run-off. They may also be used to study large-scale waves in the atmosphere and ocean if terms representing the effects of the Earth's rotation are included. See review article by Neta (1992).

Indeed, it had become customary, in developing new numerical methods for weather prediction or occanography, to study first the simpler nonlincar shallow water equations, which possess the same mixture of slow and fast waves as the more complex baroclinic three-dimensional primitive equations. One of the issues associated with the numerical solution of the shallow water cquations is how to treat the nonlinear advective terms (Cullen and Morton, 1980, Navon, 1987). In this paper the two-stage Galerkin method combined with a high accuracy compact approximation to the first derivative is used. The method was developed by Navon (1987). Sce also Navon ( $1979_{a}, 1979_{b}, 1983$ ). Our work here is to discuss porting issucs of finite element onto a massively parallel machine. Section 2 discusses the algorithm; section 3 discusses the MasPar hardware and soltware. In section 4 we detail our numcrical experiments and compare the results to the code running on the Amdahl scrial computer.

## 2. Finite Element Solution

The barotropic nonlincar shallow-water cquations on a limited-area domain of a rotating earth (using the $\beta$-plane assumption) have the following form:

$$
\begin{aligned}
& u_{t}+u u_{x}+v u_{y}+\varphi_{x}-f v=0 \\
& v_{t}+u v_{x}+v v_{y}+\varphi_{y}+f u=0 \\
& \varphi_{t}+(\varphi u)_{x}+(\varphi v)_{y}=0 \\
& 0 \leq x \leq L ; 0 \leq y \leq D, \iota>0 .
\end{aligned}
$$

Here $u$ and $v$ are the velocity components in the $x$ and $y$ directions respectively, $f$ is the Coriolis parameter approximated by the $\beta$ plane as

$$
f=f_{0}+\beta\left(y-\frac{D}{2}\right)
$$

where $\beta, f_{0}$, are constants and $\varphi=g h$ is the geopotential height. Periodic boundary conditions are assumed in the $x$ direction and rigid boundary conditions ( $v=0$ ) are imposed in the $y$-direction. The domain is a cylindrical chamel simulating a latitude belt around the carth (see c.g. Hinsman, 1975). The finite element approximation leads to systems of ODES which can be finite differenced in time (see c.g. Douglas and Dupont, 1970). In the two stage Galerkin (originally proposed by Cullen, 1974), we let any of the 4 dcrivatives in the nonlincar terms be approximated by the compact Numerov scheme, i.e. for

$$
z_{x u}=\frac{\partial u}{\partial x}
$$

we have

$$
\begin{aligned}
& \frac{1}{70}\left[z_{i+2}+16 z_{i+1}+36 z_{i}+16 z_{i-1}+z_{i-2}\right]= \\
& \frac{1}{84 h}\left[-5 u_{i-2}-32 u_{i-1}+32 u_{i+1}+5 u_{i+2}\right]
\end{aligned}
$$

Similarly for $z_{x u}, z_{y, u}$ and $z_{y z}$. The approximation of $\frac{\partial v}{\partial x}$ requires an interpolation of the boundary values

$$
\begin{aligned}
& v_{0}, v_{N+1} \\
& v_{0}=4 v_{1}-6 v_{2}+4 v_{3}-v_{4} \\
& v_{N+1}=4 v_{N}-6 v_{N-1}+4 v_{N-2}-v_{N-3} \\
& \left.\frac{\partial v}{\partial y}\right|_{1}=\frac{-25 v_{1}+48 v_{2}-36 v_{3}+16 v_{4}-3 v_{5}}{12 h} \\
& \left.\frac{\partial v}{\partial y}\right|_{N}=\frac{3 v_{N-1}-16 v_{N-3}+36 v_{N-2}-48 v_{N-1}+25 v_{N}}{12 h}
\end{aligned}
$$

This stage will require a solution of a pentadiagonal system. For the second stage, we let $w$ be any of the four nonlinear terms and we solve a tridiagonal system. For

$$
w=v z
$$

we have

$$
\begin{aligned}
& \frac{1}{6}\left(w_{j-1}+4 w_{j}+w_{j+1}\right)= \\
& \quad \frac{1}{12}\left(v_{j-1} z_{j-1}+v_{j} z_{j-1}+v_{j-1} z_{j}+\right. \\
& \left.\quad v_{j+1} z_{j}+v_{j} z_{j+1}+v_{j+1} z_{j+1}+6 v_{j} z_{j}\right)
\end{aligned}
$$

This two stage approximation yiclds $O\left(h^{8}\right)$ approximation to the derivatives $u_{x}, u_{y}, v_{x}$ and $v_{y y}$.

Now the approximation of the shallow water equations becomes
$M\left(u_{j}^{n+1}-u_{j}^{n_{2}}\right)+\Delta l\left[\left(u z_{x u}\right)_{j}^{*}+\left(v z_{y u}\right)_{j}^{*}-\int_{j} v_{j}^{\star}\right]=\Delta l \bar{K}_{21}$
$M\left(v_{j}^{n+1}-v_{j}^{n}\right)+\Delta t\left[\left(v z_{y v}\right)_{j}^{\infty}+u_{j}^{n+1}\left(z_{s w}\right)_{j}+f_{j} u_{j}^{n+1}\right]=\Delta t \bar{K}_{31}$

$$
M\left(\varphi_{j}^{n+1}-\varphi_{j}^{n}\right)-\frac{1}{2} \Delta t K_{1}\left(\varphi_{j}^{n+1}+\varphi_{j}^{n}\right)=0
$$

where

$$
\begin{aligned}
\bar{K}_{21}= & \frac{1}{2}\left(K_{21}^{n+1}+K_{21}^{n}\right) \\
\bar{K}_{31}= & \frac{1}{2}\left(K_{31}^{n+1}+K_{31}^{n}\right) \\
M_{i j}= & \iint_{A} V_{j} V_{i} d A \\
K_{1 i j}= & \sum_{k} \iint_{A} V_{i} V_{k} u_{k}^{*} \frac{\partial V_{j}}{\partial x} d A \\
& +\sum_{k} \iint_{A} V_{i} V_{k} v_{k}^{*} \frac{\partial V_{j}}{\partial y} d A \\
K_{21}^{n+1}= & \sum_{k} \iint_{A} \varphi_{k}^{n+1} \frac{\partial V_{k}}{\partial x} V_{i} d A \\
K_{31}^{n+1}= & \sum_{k} \iint_{A} \varphi_{k}^{n+1} \frac{\partial V_{k}}{\partial y} V_{j} d A
\end{aligned}
$$

$$
\begin{aligned}
K_{21}^{n} & =\sum_{k} \iint_{A} \varphi_{k}^{n} \frac{\partial V_{k}}{\partial x} V_{i} d A \\
K_{31}^{n} & =\sum_{k} \iint_{A} \varphi_{k}^{n} \frac{\partial V_{k}}{\partial y} V_{j} d A
\end{aligned}
$$

and where $V_{i}$ are the finite element shape functions.

$$
\left.u^{\times}=u^{n+1 / 2}=\frac{3}{2} u^{n}-\frac{1}{2} u^{n-1}+O(\Delta t)^{2}\right)
$$

and similarly for $v^{*}$.
Schuman (1957) filter was applicd every 12 time steps to the $v$ component of velocity in order to recover the higher accuracy of the method.

Since the two-stage Galcrkin method does not conserve integral invariants (Cullen [1979]) we apply an aposteriori technique using an augmented Lagrangian nonlinearly constrained optimization approach for enforcing the conservation of integral invariants of the shallow water cquations (see Navon and deVilliers (1983) and Navon (1983)).

## 3. System Overview

The MasPar family of massively parallel processing systems consists of arrays of 1 K to 16 K processing elements (PE), a scalar control unit (ACL) and a UNIX subsystem. Architecturally, each $P \mathcal{P}$; is a custom 64bit RISC processor with 48 32-bit registers and 64 KB of data memory. All PEs execute instructions which are broadcast from the ACD , on data stored in their local memory. Although there is only a single instruction stream, the processors have a number of autonomics, including the ability to gencrate independent addresses for indirect loads and stores to memory.

The PEs share data using two communication mechanisms: the xnet and the router. 'The xnet is an eight-way nearest meighbor mesh that is used for structured communications such as stencil operations in finite difference codes. The router is a multistage circuit-switched network for global or random communication patterns. I/O to and from the PEs is translerred via the router to an external memory buffer callod I/O RAM. From I/O RAM, data can asynchronously be translerred to a wide variety of devices such as disk arrays, frame buffers, or other machines. 'The MasPar Disk Array ( IPI )A) provides up to 22 GB of format ted capacity as a true UNIX file system. The UNIX subsystem provides the programming and run-time enviromment to users.

### 3.1 MasPar Software

The MasPar system is programmed in either MPI, a parallel extension to ANSI C, or MasPar Fortran,
an implementation of Fortran 90. In MasPar Fortran ( MPF ) parallel operations are expressed with the Fortran 90 (F90) array extensions which treat entire arrays as manipulatable objects, rather than requiring them to be iterated through one element at a time. F90 has also added a significant number of intrinsic libraries; operations such as matrix multiplication and dot product are part of the language. Since Fortran 90 is a standard defined by the ANSI/ISO commitlees, programs are architecture independent and can be transparently moved to other platforms.

$$
\begin{array}{ll}
\text { Forlran } 77 & \text { Forlran90 } \\
& \\
\text { doi }=1,256 & a=b+e \\
\text { do } j=1,256 & \\
a(i, j)=b(i, j)+c(i, j) & \\
\text { criddo } & \\
\text { cnddo } &
\end{array}
$$

The Fortran 90 code can be run on any computer with a F90 compiler. On a scalar machine such as a workstation, the arrays will be added one element at a time; just as if it had been written in Fortran 77. On a vector machine, the number of elements added at a time is based on the vector lenglth; a machine with a vector Iength of 64 will add 64 array elements at onee. 'I'he MasPar machine acts like a vector machine with a very long vector. On a 16 K MasPar machinc, 16384 arrays elements are added simultaneously.

MasPar provides key routines in math, signal, image, and data display libraries. The Math Library (MPML) contains a number of high-level linear algebra solvers, including a general dense solver with partial pivoting, a Cholesky solver, a conjugate solver with preconditioning; and an out-of-core solver. MPML also includes a set of highly-tuned linear algebra building blocks, analogous to BI AS on vector machines, from which the user can develop additional solvers. The Data Display Library provides a convenient, interface to graphically display data from within a program as it is execuling.

The MasPar Programming Environment (MPPE) is an integrated, graphical environment for developing, debugging, and tuning applications. MPPE provides a rich set of graphical tools that allow the user to interactively control and visualize a program's behavior. The statement level profiler allows the user to quickly identify the compute-intensive sections of the progrann while the machine visualizer details the use of hardware resources. Each of these tools are continuously available without having to recompile, even if a program has been compiled with optimizations.

## 4. Program

The program is modular and is complemented with easily reachable switches controlling print and plot options. The Input to the program consists of a single line containing the following six parameters:

DT - the time step in seconds ( F \%.2)
NLIMIT - total number of time steps (I5)
MF - number of time steps between printing solution (I5)

NOTTU - to print (1) or not to print (0) the $u$ component

NOUTV - to print (1) or not to print (0) the $v$ component

NPRIN T - to print (1) or not to print (0) the global nodal numbers of each triangular elements and the indices and node coordinates of the nonzero entries of the global matrix.

The main program initializes all variables and then reads the only data card of the program. It then procoeds to index and label the nodes and the elements, thus setting up the integration domain. This is done by subroutine NTMBER.

Subroutine CORRES determine the nonzero locations in the global matrix and stores them in array LOCAT. The initial fields of height and velocity are set up by subroutine INCOND. The derivatives of the shape functions ( $V_{j}$ ) are calculated in AREAA. A compact storage scheme for the banded and sparse global matrices is implemented in subroutine ASSEM. The method is based on the fact that the maximum number of triangles supporting any node is six. Three different types of element matrices ( $3 \times 3$ ) will be required for assembly in the global matrices.

A switch, denoted NSWITCH is sct for selecting between the different types of element matrices. After setting up the time independent global matrices the program proceeds to the main do-loop which performs the time-integration and which is executed once for cvery new time-step.

As the solution of the nonlinear constrained optimization problem of enforcing conservation of the nonlincar intcgral invariants requires scaling of the variables, the scaling is performed in the main program as well as in subroutine INCOND.

In the main integration loop the simulation time is set up and adjusted and then the subroutines ASSEM and MAMLLT set up and assemble the global matrices which then are added up in a matrix cquation, first for the continuity equation and in a similar manner for the $u$ and $v$-momentum cquations.

Subroutinc SOLVER then is called to solve the resulting system of linear equations (of block tridiagonal form) by the conjugate gradient square.

The new ficld values for the geopotential and velocities, $\phi_{i j}^{n+1}, u_{i j}^{n+1}, v_{i j}^{n+1}$ respectively, are used immediately as obtained in solving the coupled shallow-water equations system. For the $u$ and $v$-momentum equations, the new two-stage Numerov-Galerkin scheme is implemented. Separate routincs are set up for the $x$ and $y$-derivatives advection terms, 1 X and DY respectively. Subroutine DX implements the two-stage Numerov-Galcrkin algorithm described previously for the advective terms in the $u$ and $v$-momentum equations involving the $x$-dcrivative.

In the first stage it calculates the $O\left(h^{8}\right)$ accurate generalized-spline approximation to the $(\partial u / \partial x)$ first dcrivative by calling upon subroutine CYCPNT which solves a periodic pentadiagonal system of linear equations generated by the spline approximation.

In the second stage it implements the second part of the Numerov-Galerkin algorithm for the nonlinear advective term $u(\partial u / \partial x)$ and solves a cyclic tridiagonal systcm by calling upon subroutinc CYOTRD. Subroutine DY implements the two-stage NumerovGalerkin algorithm described previously for the advective terms in the $u$ and $v$-momentum equations involving the $y$ - derivative. In its first stage it calculates the $O\left(h^{8}\right)$ accurate gencralized-spline approximation to the ( $\partial u / \partial y$ ) first derivative by calling upon subroutine PENTDG which solves the usual pentadiagonal system of linear equations generated by the generalized-spline approximation.

In the second stage subroutine DY implements the second part of the Numerov-Galerkin algorithm for the nonlinear advective term $u(\partial u / \partial y)$ and solves the Galcrkin product by calling upon subroutinc NCTRD to solve a special tridiagonal system.

The boundary conditions are implemented by subroutine BOUND. Periodically, a Schuman filtering procedure is implemented for the $v$-component of velocity only, by calling subroutine SMOOTII. The integral invariants are calculated at cach time-step by calling subroutine LOOK. If the variations in the intcgral invariants excecd the allowable limits $\delta_{E^{\prime}}, \delta_{11}$, or $\delta_{Z}$, the Augmented-Lagrangian nonlinear constrained optimization procedure is activated. The unconstrained optimization uses the conjugatc-gradient subroutine E14DBF of the $\operatorname{NAG}(1982)$ scientific library. Subroutine E14DBF calls a uscr-supplicd subroutine F'LVCI which evaluates the function value and its gradient vector as well as subroutine MONIT whose purpose is mercly to print out different minimization parameters.

After a predetermined number of steps, subroutine OUT is called, which in turn calls upon the subroutines LOOK to calculate the integral invariants. Practically 4-5 augmented-Lagrangian minimization
cycles were determined to be sufficiont.
We ran the program under MPPE and the following table shows the CPC time used by some of the routines. All others require less than $5 \%$ each. Therefore we have decided to parallelize ASSEM, MAMLLT,

| Routincs | CPU |
| :--- | ---: |
| SOLVER | $32 \%$ |
| ASSEM | $25 \%$ |
| MAMULT | $14 \%$ |
| CORRES | $5 \%$ |
| BOUND | $5 \%$ |

'Table 1: CPU time used by some routines
SOINER (switching from Gauss Seidel to Conjugate Gradient Square). Other subroutines we parallelized are:

## CORRES, INCOND, LOOK, MONIT, NUMBER. and AREAA.

After this, the most time consuming routines become E14DBF and FUNCT. These are required only if the integral constraimls are not conserved. Therefore if the mesh is fine, these routines will not be called. Our numerical experiments confirmed that these two routines were called only in the coarsest grid case.

The next set include: DX, DY, CYCTRD, CYCPNT, NCTRD, PENTDG, TRIDG, and SMOOTH. We have decided not to try at this point to paralIclize these or BOUND. We have ran this program on the MP-1104 (4096 processors) on a variety of grid sizes. The original program was also ran on the Amdahl 5990/500 scrial computer. All computations were performed in double precision. The domain is a rectangle 6000 km by 4400 km . The coarsest mesh, $\Delta x=\Delta y=400 \mathrm{~km}$. This means that the number of grid points in the $x$-direction, $\mathcal{N C}^{-} \mathrm{C}$, is 15 and the number of grid points in the $y$-direction, NROW is 11. ( $\Delta t$ will be adjusted for stability.) The number of time steps, NLIMIT, is 30 .

The initial condition for the height field is given by

$$
\begin{aligned}
h(x, y)=H_{0} & +H_{1} \tanh \frac{9(D / 2-y)}{2 D} \\
& +\frac{H_{2}}{\cosh ^{2} \frac{9(D / 2-y)}{2 D}} \sin \frac{2 \pi x}{L}
\end{aligned}
$$

| DIM | $\Delta x$ | $\Delta t$ | Amdahl | MP-1104 |
| ---: | :--- | :--- | :--- | :--- |
| $15 \times 11$ | 100 | 18. | 1.14 | 14 |
| $18 \times 45$ | $133 \frac{1}{3}$ | 5.51 | 13.52 | 31.3 |
| $63 \times 62$ | 93.75 | 4.22 | 24.8 | 44.3 |
| $88 \times 85$ | 51.76 | 3.03 | 48.32 | 80 |
| $128 \times 125$ | 46.87 | 2.10 | - | 164 |

Table 2: Total CPC time in sec for several grids
where

$$
H_{0}=2000 m, \quad H_{1}=-220 \mathrm{~m}, \quad H_{2}=133 \mathrm{~m}
$$

and

$$
f_{0}=10^{-4} \sec ^{-1}, \quad \beta=1.5 \times 10^{-11} \sec ^{-1} \mathrm{~m}^{-1} .
$$

This initial condition is given in Grammeltveldt (1969) and tested by several researchers (Cullen and Morton (1980), Gustafsson (1971), Navon (1987) etc.) The initial velocity fields were derived from the initial height field via the geostrophic relationships

$$
\begin{aligned}
u & =-\frac{g}{f} \frac{\partial h}{\partial y} \\
v & =\frac{g}{f} \frac{\partial h}{\partial x} .
\end{aligned}
$$

'lable 2 gives the CPU time for each grid.
If we compare the CPt time for three of the subroutines we parallelized (to avoid the difficulty that some parts are still running on the front end) we find that in MAMULT and SOLVER we were able to cut the CPL time. The results are summarized in 'Table 3.

The code was ran under profiler and we found that now the CPU usage (in percent of total CPUJ) is as given in table 4.
It is clear that one should parallelize DX,DY,PENTDG,TRIDG and LOOK. The first four refuire that one parallelizes the subroutines NCTIRID,CYCTRI and CYCPN'I. This is not done since the tridiagonal and pentadiagonal systems to be solved are of order NC. We feel that one should approach this problem slightly differently. Instead of trying to parallclize this code which is of high order, we should parallelize a low order finite element code for the shallow water cquations. The accuracy of the

| Subroutine | Problem size | Amdahl | MP- 1104 |
| :--- | :---: | ---: | ---: |
| ASSFMM | 48 by 45 | 3.02 | 5.77 |

## Conclusion

We have developed a high order finite element code to solve the shallow water equations on the MasPar massively parallel computer MP-1104. It is believed that a low order finite element code will be more eflicient on the MP-1101 computer.

## Acknowledgement

The first author would like to thank MasPar Computer Corporation for the computer time used to develop the code. This research was conducted for the Office of Naval Rescarch and funded by the Naval Postgraduate School.
