# Rapid Prototyping Languages for Expert Systems

*Luqi*

Computer Science Department  
Naval Postgraduate School  
Monterey, CA 93943

## 1. Introduction

Work on rapid prototyping languages is aimed at reducing software development costs via prototyping. A software prototype is an executable initial version of a proposed system. Prototypes are built to assess whether a proposed system will be acceptable to its users and whether a proposed design will provide adequate functionality and performance. A prototype is constructed prior to the production version of the system for the purposes of

- (1) gaining information to guide analysis and design, and
- (2) supporting the generation of the production version.

To be useful, the prototype must be constructed quickly and at low cost. Thus a prototyping language must make it easy to construct, modify, and instrument prototypes, possibly at the expense of efficiency, completeness, capacity, or robustness. Prototyping is especially useful for large systems or novel application areas. Expert systems often fall in the latter category.

Rapid prototyping languages are intended to support a comprehensive set of tools for computer-aided software design and prototyping. The goals for such a language and the associated prototyping system are:

- (1) Rapid construction and adaptation of software,
- (2) Enabling the development of more powerful systems,
- (3) Checking if specified systems are acceptable to users,
- (4) Checking internal consistency of proposed designs, and
- (5) Ensuring that implementations conform to specifications.

In this paper we discuss the principles of language support for rapid prototyping, based on our experience with the design of a prototyping language and the feasibility study for its implementation over the past five years. We examine some of the basic issues involved in the design of a rapid prototyping language, with attention to issues involving the prototyping of expert systems.

## 2. Requirements for a Comprehensive Prototyping Language

The goal of developing a general purpose prototyping language is very ambitious, and requires solutions to some open research problems for complete fulfillment. Prototyping has potential benefits for large software systems, many of which are concurrent, distributed, and exhibit hard real-time constraints. Expert systems are being implemented with concurrent and distributed configurations, and there is a growing demand for expert systems capable of meeting hard real-time constraints. In this section we discuss the general properties of a comprehensive prototyping language.

A prototyping language should have a clear and simple structure and semantics to make it easy to learn, understand, and process mechanically and rapidly. This implies uniform structure, a small number of orthogonal constructs, and general interpretations without special cases or restrictions. To support automated tools, the language should have an abstract syntax and an unambiguous and precisely defined meaning. The underlying model should have a mathematical basis to support execution, analysis, verification, and trusted transformations. In particular, the semantics of the language should support rigorous reasoning about the properties of prototypes described in the language and transformations on expressions of the language. The language should also support a user interface for communication with untrained people, with graphical summary views, English paraphrasing, and explanation facilities.

A prototyping language should be expressive. It should be easy to use the language to construct concise and clear descriptions for a wide variety of systems. This implies language support for abstractions, uniform communication, logical inference, incomplete descriptions, and automated design completion. In addition to providing traditional facilities for functional, data, and control abstraction, the language should also support abstractions for concurrency, synchronization, and timing constraints. The language should be at a specification and design level rather than at a programming level: the constructs of the language should correspond directly to decisions made by the designer, rather than to operations performed by the processor. This will make prototype descriptions self-documenting and easy to change. The language should allow the designer to specify only selected attributes. This requires automatically supplying default values for all attributes needed for execution of a software prototype. The language should be capable of constructing the software tools in its own prototyping environment.

To support large scale prototypes, system evolution, and parallel execution, a prototyping language should have mechanisms for localizing design decisions in the description and localizing interactions between system components or pieces of knowledge in the knowledge base. These features allow independently designed subsystems of complex expert systems to cooperate without unexpected interference.

To support user validation and system evolution, a prototyping language should support a facility for maintaining the correspondence between requirements and design decisions. Tools will be needed for determining which parts of a description must be removed or modified when a requirements change removes the support for previously made design decisions. The language should provide a harmonious interface to such tools.

Facilities in a prototyping language for recording black-box specifications provides the benefits of a specification language. They support prototype component documentation, verification via proofs and automated testing, and queries for reusable component retrieval. They also form the basis for automated synthesis capabilities, inheritance of common properties and constraints, and consistency checking. For expressiveness, this part of the language may contain non-computable constructs such as quantifiers ranging over unbounded sets. The language should support facilities for describing clear-box characteristics of designs such as interconnections of available components, dependencies between components, design goals such as invariant constraints or bounding functions, and design justifications such as criteria for choosing between alternative designs.

The language should have a distinguished executable subset that is easily recognizable, both by human users and automated tools. Every expression in this distinguished subset should be executable for all possible initial conditions, although some expressions may denote non-terminating computations. The distinguished subset need not contain all of the executable expressions, and expressions outside the distinguished subset may be partially executable, in the sense that execution may fail under some conditions. It should be possible to either augment or transform expressions of the language outside the executable subset to make them executable.

Besides supporting queries for retrieval of reusable software components, the language should have facilities for adapting components to new uses and making small perturbations on their behavior without examining the details of the internal implementation of the components.

To support high productivity, the language should support the construction of efficient implementations by augmenting the prototype description with annotations describing additional constraints or lower level design decisions. This enables the designer to view optimization as a refinement step where additional information is added to the original descriptions, rather than a complete reformulation of the system description. Such an approach saves designer time by avoiding repeated treatment of the same issues in different ways, and by reducing the opportunities for making transcription or translation errors.

Efficiency is more of a concern for the production version of the system than for the prototype, but it cannot be ignored because it must be possible to run test cases and gather data in a reasonable amount of time. This implies that execution mechanisms based on exhaustive enumeration are insufficient to meet the requirements of a prototyping language, although they may be supplied as a default to allow running small test cases in the absence of information about more efficient execution strategies. The language should therefore provide a set of fairly efficient execution mechanisms, tools for locating performance bottlenecks in larger systems, and incremental optimization transformations to improve prototypes that are impractically slow.

Real-time constraints impose a slightly different set of subgoals: execution times must be predictable, although not necessarily very fast. Prototypes of real-time systems may operate in simulated time or linearly scaled real time, but the actual execution times for the production version must be predictable within accurate bounds. The presence of real-time constraints severely restricts the kinds of computations a system may perform, and in the case of expert systems, limits the amount of logical inference that can be performed. The design of expert systems that operate within real-time constraints is a largely unexplored area, and significant research progress is needed in this area to fully realize the goals of a comprehensive prototyping language.

The rapid construction of software prototypes depends on simplifying the view of the system through which the specifiers and designers do their work, and providing automated means for bridging the gap between this simplified view and the detailed programming level description currently needed to make a software system efficiently executable. This automated support should include mechanisms for execution, static analysis of the properties of the proposed system, preparation of test cases, reporting and analyzing results, and diagnosing ill-formed descriptions and departures from desired behavior to allow the specifiers and designers to work entirely within the simplified view, at least during the construction of the initial prototype. While the construction of the tools is not a required until later phases of the project, supporting the construction of such a tool set is a major driving force for the language design. The development of an integrated set of tools requires a consistent and simple semantic model rich enough to express and support all of these functions. Finding suitable models is the key to the project.

### 3. Modeling Issues

The models underlying the language provide the common ground for the associated set of tools. The semantic model for the language provides the basis for automated analysis, while the computational model provides the basis for execution. One of the main challenges in this project is to find a model that can coherently span the range of applications required. This will require a significant advance in the state of the art.

There is no single common model of expert systems available for rapid prototyping. First order logic is one of the most familiar models for reasoning, but it has been criticized for its weaknesses, such as lack of facilities for handling uncertain information, representing heuristic methods for speeding up conclusions, and non-monotonic reasoning. Many other kinds of logic have been proposed, but the theories of these logics are still being explored and there has been no consensus on whether there is a single logic suitable for constructing all types of expert systems, or which variety of logic is the most promising. There are also approaches to expert systems that are based on models other than logic, such as semantic networks, Bayesian statistics, and production systems. Since it is not clear which approach will yield the best results in the long run, a comprehensive prototyping language must find a unified way of treating most of the issues raised by this diverse set of models.

There is also no single commonly accepted model for representing real-time constraints. Some approaches that have been explored include temporal logic, state machines, mode charts, augmented data flow diagrams, Petri nets, and I/O automata. The model for a comprehensive prototyping language should be chosen to enhance the application of recent results in logic, graph theory, and combinatorics to link the semantic model to an effective execution mechanism. Other unexplored areas include effective models for real-time databases and real-time communications networks. In both of these areas, the problems of providing service within guaranteed worst-case time bounds are largely unexplored.

### 4. Supporting the Design of Expert Systems

Several special purpose systems for supporting the design of expert systems have been developed, some of which are known as expert system shells. A comprehensive prototyping language should improve on available facilities if possible, and integrate them with facilities suitable for producing other kinds of software. There are two ways of supporting the prototyping of expert systems: (1) adding special purpose features to the prototyping language, and (2) adding predefined reusable software components that can be defined within a general purpose language, such as specialized data types, state machines, and functions. The predefined component approach is preferred to the addition of specialized language features because of the requirement for simplicity. However, such predefined components should have standardized interfaces to improve portability.

Many of the standard building blocks for expert systems can be provided as generic predefined components. These include facts, rules, patterns, frames, contexts, constraints, demons, instance generators, pattern matchers, unification mechanisms, and forward and backward chaining inference engines. Standardization requires careful analysis of these components and specification of their required properties. An open issue is whether current mechanisms for defining generic components are flexible enough to adequately capture the range of behavior required for these kinds of components, and if not, what extensions are required.

Some of the requirements for a prototyping language are determined by the need for prototyping expert systems. Examples of such requirements are

- (1) a means for conveniently defining external representations and input facilities for the knowledge in the knowledge base,
- (2) support for the first class treatment of higher order objects such as types, functions, tasks, and generators, and
- (3) support for control mechanisms such as state-triggered demons, backtracking, run-time control over task priorities, and scheduling of temporal events.

It is important to meet these requirements in a prototyping language for expert systems.

## 5. Knowledge Base Issues

Knowledge base management is an important part of the design of expert systems. Rapid prototyping of knowledge based systems brings special requirements for the design of a prototyping language as well as its environment. Expert system technology is useful in implementing parts of the supporting environment for a prototyping language. For example, such an environment needs knowledge base support for the following functions:

- (1) Managing reusable components. The environment should contain a large software base with reusable components. This software base should be coupled with a set of rules for tailoring and combining available components to fulfill queries that do not exactly match any of the components explicitly stored in the software base.
- (2) High level debugging. Errors and failures during prototype execution should be mapped from the programming language level to level of the prototyping language, to allow the designer to work entirely in terms of the semantic model associated with the prototyping language.
- (3) Optimization. The transformations for optimizing a prototype version of a system to produce a production version should be performed with minimum interaction with the designer. This implies keeping track of the decisions made by the designer in optimizing previous versions of the system, determining which of those decisions are still valid for later versions, and automatically applying the ones that are found to be still valid.
- (4) Explanations. Justifications for decisions made automatically should be available to provide feedback to the designer in cases where automated design completion procedures fail. This requires an expert system with a substantial knowledge base.

These needs indicate that the prototyping system associated with a comprehensive prototyping language will need expert system technology for realizing some of its major subsystems.

## 6. Conclusions

DARPA/ISTO has made an important decision to develop designs for a rapid prototyping language for software systems, which is intended to apply to a variety of large software systems, including knowledge-based systems, parallel systems, distributed systems, and real-time systems. The Common Prototyping Language project has an ambitious set of goals that raises many interesting research problems, many of which involve expert systems. Solutions to these problems are essential for achieving significant improvements in the quality and productivity of the software development process.

The proposed connection between the Common Prototyping Language and Ada raises several issues that must be considered. Goals for the Common Prototyping Language include computer-aided transformations of prototypes into Ada implementations of the production version of the software, and eventually implementing the tools in the prototyping system in Ada to provide portability. This poses a problem

because ordinary compiler technology is insufficient for execution of the prototyping language. The need for flexibility and run-time handling of newly created types and procedures to support expert systems also provides challenges for efficient implementation techniques in terms of Ada. Conventional translation techniques must be coupled with facilities for scheduling to meet hard real-time constraints with transformations to allow the execution of incompletely specified processes, and access to an interpreter or an incremental compiler at run-time.

Ada provides a completely static type system, treats types and functions as second class objects, and requires task priorities to be known at compilation time. It is clear that the flexibility required for supporting expert systems development can be provided by adding a run-time interpreter on top of the Ada language. The difficult problem will be to provide these features efficiently, and without introducing excessive run-time overheads for portions of the prototype that do not require flexibility beyond that provided directly by Ada.

Ada provides relatively weak guarantees about the scheduling of tasks, and limits programmer control over scheduling to statically specified priorities. Since this is somewhat removed from the level of support needed for implementing hard real-time systems, the execution support system for the prototyping language will have to provide higher level facilities for scheduling real-time operations. Such facilities can be classified as on-line (done at run-time) and off-line (done prior to execution). There is no universally accepted approach to real-time scheduling. Optimal scheduling algorithms are very time consuming, and generally cannot be carried out on-line, while off-line approaches are inflexible and do not handle overload situations very well. There are many different scheduling algorithms, and choosing the best one for a given application is a difficult problem.

Transformations are needed to execute incompletely specified components. Such transformations should supply reasonable default values for attributes necessary for execution if the designer does not explicitly specify them. Such attributes can be explicitly specified to produce a more accurate model of the system or to improve its performance. One example of such attributes is the assignment of tasks to physical processors. Sometimes the assignment of particular critical tasks to particular processors is necessary to meet tight timing constraints by avoiding the overhead of some interprocessor communication. However, the designer usually does not care about the placement of all tasks, and would like the system to assign reasonable default locations to all of the tasks that do not have explicit processor assignments.
