13. ABSTRACT (maximum 200 words) JELO is an Excel spreadsheet model of joint expeditionary logistics operations and allows end-to-end analysis of the options for closing forces from CONUS, through the sea base, to objectives ashore. Sustainment operations are included. The model is flexible and, while the examples in the report involve the 2015 Marine Expeditionary Brigade, all model parameters may be user specified. The MPF(F) is the subject of current discussion and analysis to determine what its capabilities and capacities need to be. Additionally, there are potentially other platforms to build in order to make Sea Basing a reality—high-speed connectors, assault connectors, and rapid strategic lift ships. JELO can be of use in evaluating the alternatives.

JELO: A Model of Joint Expeditionary Logistics Operations

Executive Summary

Joint expeditionary logistics operations are required in Sea Basing. Forcible entry operations are initiated and sustained from ships operating as a sea base until the operation is successfully concluded or until heavier joint forces arrive at the ports and airfields secured by the forcible entry operations. This is very different from traditional ground combat operations initiated from and sustained by bases ashore; e.g., Operation Desert Storm (ODS) and Operation Iraqi Freedom (OIF).

Sea Basing expeditionary maneuver forces for combat operations ashore involves 1) closing troops from CONUS to the sea base, 2) force assembly at the sea base, 3) deployment of forces from the sea base to objectives ashore, and 4) sustainment of the forces ashore and ships of the sea base. These fundamental operations can be performed in a variety of ways.

The sea base consists of one or more carrier strike groups (CSGs), one or more expeditionary strike groups (ESGs), combat logistics force ships, and maritime preposition force (future) (MPF(F)) ships. The unit equipment and combat stores of the maneuver forces are prepositioned forward on the MPF(F) ships. Troops (and non-self-deploying aircraft) from CONUS must close to the MPF(F) ships. In closing troops and in sustainment there is the notion of an advance base whose availability is assured, but may be up to 2,000 nm from the sea base. If large, fixed-wing transport aircraft cannot land on ships at sea, troops may need to be transported to the advance base as an intermediate step in closing to the sea base. Troops could be transported from CONUS to the advance base either by aircraft or by ships. Whereas aircraft cannot proceed directly to the sea base, ships from CONUS could steam either to the advance base or to the sea base. The MPF(F) ships could steam directly from their preposition site to the sea base or to the advance base.

If the troops are transported from CONUS to the advance base by aircraft and the MPF(F) ships do not call at the advance base to onload them, a connector vessel must transport them from the advance base to the MPF(F) ships. If the troops are transported from CONUS to the advance base in rapid strategic lift ships (RSLs) and the MPF(F) do not call at the advance base, a connector is again needed to take the troops from the advance base to the MPF(F) ships. Alternatively, the RSLs could transport the troops from CONUS to the MPF(F). The troops could transfer to the MPF(F) ships either at the sea base or while the MPF(F) and connector or RSLs are en route to the sea base, if this is feasible. An option that eliminates the need to transfer troops between ships in open ocean is to have the MPF(F) ships call at the advance base and onload troops at the pier. A convenient scenario may be that the advance base is the port where the MPF(F) ships are prepositioned.

Clearly there are a variety of ways of closing troops to the sea base. Sea Basing capability requires new preposition ships and possibly RSLs and/or high-speed connectors (HSC). Analysis is required to choose between the various alternatives and the platforms that enable them. One measure of performance of any alternative is the time it takes to close troops to the sea base or the time it takes to close to the sea base and deploy to objectives ashore.

JELO is an expected value Excel spreadsheet-based model that represents a number of closure alternatives, transfer, deployment, and sustainment. Most of the flows and rates are treated as parameters characterized only by their expected values. Whether the flow is the transfer rate of personnel from a HSC to a MPF(F) ship or the rate is the consumption of ammunition by forces ashore, only deterministic planning factors are available for current operations and systems and only goals are available for future systems. Analysis more sophisticated than expected value analysis requires treating many of these parameters as random variables and requires specification of the mean, variance, and distribution of the parameters. Such data is generally unavailable for current, as well as future, capabilities and systems.

The model is transparent, clearly indicating its structure and logic. It is not practical to build a completely general model that encompasses all the alternatives. An analyst familiar with JELO can build on the basic structure to represent any operations of interest. The goal has been to create a useful tool for examining and evaluating various sea basing architectures. Examples are shown only to demonstrate use of the model.

The Navy and Marine Corps are currently defining the MPF(F). Additionally, there are potentially other platforms to build in order to make Sea Basing a reality—high-speed connectors, assault connectors, and rapid strategic lift ships. The goal has been to develop a model that the OPNAV staff can use to provide insight about sea basing operations, end-to-end, and support programmatic decision-making.

1. Introduction

While ground combat operations in Operation Iraqi Freedom in the Spring of 2003 were very successful, a pause in the fighting was called on about the 29th of March—eight or nine days after the operation began—because the 3rd Infantry Division and the 1st Marine Expeditionary Force (I MEF) forces were low on MREs, fuel, and ammunition. These units were being resupplied through the movement of these commodities over the ground from depots also on the ground in Kuwait. In Sea Basing, forces will arrive to ships of a sea base, assemble with their equipment and stores at sea, deploy from ships of the sea base to objective areas ashore and conduct combat operations. Their resupply will flow from ships of the sea base. As difficult as it was to deploy and resupply forces in Iraq from bases and depots ashore, sea basing such operations will be much more difficult and require a system of systems consisting of preposition ships, high-speed sealift ships, high-speed connector vessels, the means to transfer troops, equipment, stores between platforms in open ocean, and air and surface connectors for deploying and resupplying the forces.

Figure 1 depicts one of a large number of ways of closing troops and non-self-deployed aircraft to the sea base, specifically to the MPF(F) ships. Only the MPF(F) ships in the sea base have the maneuver force unit equipment and stores and can accommodate the troops on-board. Unless the MPF(F) call at the advance base, a transfer is required to move the troops and cargo to the MPF(F) ships. The figure also reflects the deployment of the maneuver forces to objectives ashore from the MPF(F) ships after their arrival and assembly. There is another transfer operation in which the troops and their equipment and stores are loaded from the MPF(F) to connectors that take them from the sea base to objective areas ashore. These connectors may be aircraft or surface craft. Finally, the figure indicates resupply of the forces ashore and of the ships of the sea base including not only the MPF(F), but the ships of associated carrier strike groups (CSG) and expeditionary strike groups (ESG) as well.

The focus here is on flowing forces to, and subsequently deploying from, the MPF(F). ESG operations are not modeled though the Marine Expeditionary Unit (MEU) battalion landing team could be part of the operations.

A common definition of military logistics is that it is the set of activities concerned with the establishment, maintenance, and movement of forces. It follows then that expeditionary logistics operations encompassing the closure of troops to the sea base, the assembly of force units, the deployment of these forces to objectives ashore, and the resupply of all concerned—forces and ships—should be described as Joint Expeditionary Logistics Operations, and the model itself named JELO.

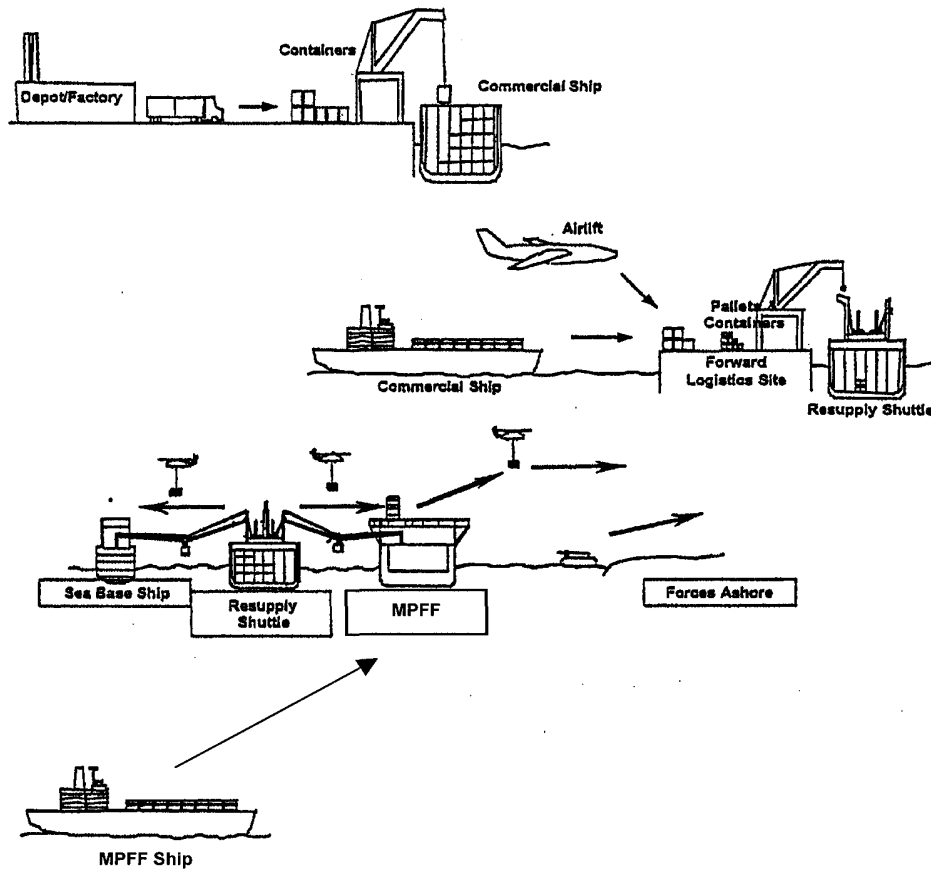

Figure 1. Expeditionary Logistics Operations

2. Assumptions, Data, Planning Factors, and Uncertainties

The first assumption is really about the scenario reflected in the model. It includes the flow of an MPF(F) Marine Expeditionary Brigade (MEB) to MPF(F) ships at a sea base. The MPF(F) MEB troops that flow to the sea base are the Seabased Maneuver Element (SBME) and the Seabased Support Element (SBSE), plus a Naval Support Element (NSE). The SBME and some direct support from the SBSE are subsequently deployed from the MPF(F) ships to objective areas ashore. The SBME consists of three reinforced infantry battalions of which one is intended for vertical deployment and two are to be deployed on the surface. The Vertical battalion is to be lifted 110 nm to an objective inland and the Surface battalions will be carried 25 nm to the shore with the beach as their initial objective.

There are several ways to move the troops of the SBME, SBSE, and NSE from CONUS to the sea base and a few of these are described in Section 5. Aircraft will not be

prepositioned on the MPF(F) and non self-deploying aircraft will have to be airlifted into the theater. The tiltrotor aircraft will self-deploy. LCACs and EFVs will be prepositioned on the MPF(F) ships. An advance base may be used in the flow of forces to the sea base. The advance base must be a facility with an airport and a seaport, and controlled by the United States through ownership or treaty. While we probably know where the MPF(F) squadrons will be prepositioned, we don't know where the sea base will be required and what advance base will be utilized. Troops flown to the advance base may be transshipped by high-speed connector (HSC) vessels from the advance base to the sea base. The capabilities of the HSC are unknown and it is not yet a program of record. All we know about it is that the Initial Capabilities Document for a High Speed Connector [2] states that they will reside in the numbered fleets and be forward deployed in the geographical combatant commander's areas of responsibility in order to provide responsive support to the Combatant and Joint Force Commanders. In order to include the HSC in this modeling, some assumptions have to be made about the numbers of such vessels and their speed, range, and capacities for transporting troops, cargo, and aircraft.

Once the HSCs arrive at the sea base or earlier, their troops must be transferred to the MPF(F) ships. All Concept of Operations (CONOPS) documents note the requirement for such transfer capabilities, but none say how this capability is achieved and this requires assumptions for modeling purposes. An alternative way of flowing maneuver forces to the sea base is for them to embark rapid strategic lift ships (RSLS) in CONUS and sail to the advance base or directly to the sea base. Again, such high-speed shipping is not a program of record and one has only available PowerPoint briefings that bracket achievable speeds and ranges without commenting on capacities, aircraft operational spots, etc.

Perhaps the largest assumptions involve the MPF(F) itself because it is so central to sea basing. While the Analysis of Alternatives has been completed [3], there are a number of ship and squadron alternatives, and no doubt more alternatives yet to come. Though a program of record, the MPF(F) ship's basic characteristics (things like speed, number of aircraft operating spots, number and type of surface connector loading points, etc.) are as yet undetermined. Again, for modeling purposes, assumptions have to be made. The assumption is that there are eight like ships in the MPF(F) squadron, all with a single aircraft operating spot and single surface connector load point. From [3], the distributed capability designs have four or five aircraft operating spots per ship, while the specialized ship designs have one or two aircraft operating spots per ship. MPF(F) ship speed, number of spots, and surface craft load points in a squadron are treated as parameters and the JELO user can input the numbers or range of numbers of interest.

The maneuver forces on the MPF(F) are deployed ashore to conduct a forcible entry operation in which they will use combat stores at assault rates for the first five days and at sustained rates for another 15 days. The MPF(F) is to have stores for 20 days of operations [3]. If the 20 days of supply is in terms of the full MEB, stores on the MPF(F) will support just the SBME, SBSE, and NSE for even longer. The assumption is that either the operation achieved all objectives and is ended or that by the 20th day joint

heavy forces arrived in number through the air and sea ports secured in the forcible entry operation.

Data—hard data—exists for very little of the overall problem. There is operational or test data available for the LCAC and the MV-22. It cannot be known from the available literature whether the EFV speed on water should be assumed to be 20 kts or the long-advertised 25 kts. It is known that sea state affects the LCAC's speed and payload and that it cannot operate at all above sea state 4 [4]. What the mission-capable rates of the various connectors will be over time are not known, though there is an estimate for the LCAC [4] and other studies have made assumptions about the MV-22 and CH-53E mission-capable rates in sustained operations.

OPNAV N42 and Fleet Forces Command are compiling logistics planning factors from a number of sources and selecting and documenting approved numbers [5]. If all analyses use the same inputs, comparing the results should be possible.

These considerations apply as well to Marine maneuver forces. The 2015 MPF(F) MEB is different in numbers, kinds of units, and table of equipment from the Marine Corps Bulletin 3501 MEB. The published logistics planning factors for the consumption of fuel and ammo are based on the MCB 3501 MEB or even earlier versions. Logistics planning factors for the 2015 MEB have yet to be published.

The methodology adopted for estimating SBME daily fuel and ammo requirements is to take the existing planning factors and the existing table of organization personnel numbers for each type of unit (infantry battalion, artillery battery, LAV company, etc.) and compute the commodity use planning factor in terms of pounds or gallons per Marine per day. These factors are then applied to the SBME table of organization for each of the three reinforced infantry battalions and their direct support personnel. This methodology produces smaller daily requirements for fuel and ammo than most of the numbers in the literature, but are perhaps consistent with the changes being made by the Marine Corps to sea base smaller, lighter maneuver forces.

3. The Maneuver Force

The maneuver force modeled is the 2015 MPF(F) Marine Expeditionary Brigade (MEB) [1]. While the 2015 MEB is always 14,484 troops, whether it is an amphibious MEB or an MPF(F) MEB, the MPF(F) MEB consists of a Seabased Echelon of 8,062 troops plus a Naval Support Element and only the Seabased Echelon is flowed to the sea base. The Seabased Echelon consists of the Seabased Maneuver Element (SBME) and the Seabased Support Element (SBSE). Most of the SBSE and all of the NSE stays aboard the MPF(F). The Assault Element/Direct Support CSS that is deployed ashore is composed of a reinforced battalion-sized maneuver element configured for vertical lift and two reinforced battalion-sized maneuver elements configured for surface lift. The battalion to be vertically deployed consists of 1,164 troops whose major equipment includes 28 LAVs, 8 EFSS, and 143 HMMWV variants. The battalions to be surface deployed each consist of 1,840 troops with 53 EFVs, 14 M1A1 tanks, 28 LAVs,

6 LW155 artillery pieces, 6 HIMARSs, 157 HMMWV variants, 45 MTRVs, and 18 LVSs. The unit equipment and most of the supporting combat stores are prepositioned on the MPF(F) ships.

4. The Maritime Preposition Force (Future)

The requirements of MPF(F) have been examined in detail and a number of alternative designs were presented in the MPF(F) Analysis of Alternatives [3]. Still, the Navy Research Advisory Committee, in its report on Sea Basing to ASN (RD&A) on 5 August 2004, said the “MPF(F) vision is unclear, there are too many unknowns, and it is not ready to build.” This is reflected by the fact that construction was delayed from 2007 to 2009. However, in order to proceed with modeling, some assumptions about the MPF(F) are necessary.

It will be assumed that the MPF(F) squadron will consist of identical (distributed) ships. This will avoid what the Marines call a “single point of failure.” The number of such ships in the squadron need not be explicitly specified. Instead, the user specified input parameter is the number of aircraft spots in the squadron and the number of surface connector loading points in the squadron. Ship speed is also a user specified input parameter. It is assumed that the squadron of MPF(F) ships can accommodate at least 8,500 troops collectively. Also implicit is that the design of the MPF(F) is such that it collectively can carry all the needed unit equipment for the MEB, 20 days’ supply of all stores including fuel and ammunition, has assembly areas of sufficient size, and has selective offload capability. Further assumptions are that the MPF(F) ships will collectively have 16-20 LCACs, 48 MV-22 tiltrotor aircraft, and 20 CH-53X heavy-lift helicopters [3]. The LCACs will be prepositioned on the MPF(F) ships, but the aircraft will have to deploy to the MPF(F). The MV-22s will self-deploy and the non-self-deploying CH-53X and AH/UH helos will be transported to the sea base [3]. The LCAC is the surface connector because there is no other surface connector likely to be available in 2015. The LCAC is characterized by its speed as a function of sea state, range, and transport capabilities (vehicle and troop capacities, loading and unloading times). Connectors that might be available in 2020 or 2025 can be incorporated by changing the characteristics of the deployment connector.

The question of where the connectors (air and surface) are on C-day is critical. The aircraft are not prepositioned and must self-deploy or be transported to the sea base [3]. If HSC vessels are utilized, the assumption is that they were forward deployed with the numbered fleets and thus available in theater [2]. The LCAC is the other major connector and [3] speaks of it being organic to the MPF(F) and indeed it’s cost is included in the sea base total ownership cost.

5. Closing Forces to the Sea Base

There are many possibilities for closing forces to the sea base. Troops (and non-self-deploying aircraft (NSDA)) from CONUS must close to the MPF(F) ships of the sea base. In closing troops and in sustainment there is the notion of an advance base

whose availability is assured, but may be up to 2,000 nm from the sea base. If large, fixed-wing transport aircraft cannot land on ships at sea, troops need to be transported to the advance base as an intermediate step in closing to the sea base. Troops could be transported from CONUS to the advance base either by aircraft or by ships. Whereas aircraft cannot proceed directly to the sea base, ships from CONUS could steam either to the advance base or to the sea base. The MPF(F) ships could steam directly from their preposition site to the sea base or to the advance base.

If the troops are transported from CONUS to the advance base by aircraft and the MPF(F) ships do not call at the advance base to onload them, a connector vessel must transport them from the advance base to the MPF(F) ships. If the troops are transported from CONUS to the advance base in rapid strategic lift ships (RSLs) and the MPF(F) do not call at the advance base, a connector is again needed to take the troops from the advance base to the MPF(F) ships. Alternatively, the RSLs could transport the troops from CONUS to the MPF(F). The troops could transfer to the MPF(F) ships either at the sea base or while the MPF(F) and connector or RSLs are en route to the sea base, if this is feasible. An option that eliminates the need to transfer troops between ships in open ocean, is to have the MPF(F) ships call at the advance base and onload troops at the pier. A convenient scenario may be that the advance base is the port where the MPF(F) ships are prepositioned.

NSDA must also be considered. The NSDA will include the heavy-lift helicopters (CH-53X) and the tactical helicopters (AH-1 and UH-1). If carried from CONUS to the advance base in cargo aircraft (C-17), they must be partially disassembled prior to loading and then reassembled and flight checks performed prior to being operational. These things add considerable time to the closing process. If the NSDA can be flown to RSLs and transported in folded, but not disassembled condition, considerable delay can be avoided.

Clearly there are a variety of ways of closing troops and NSDA to the sea base. Sea Basing capability requires new preposition ships and possibly RSLs and/or high-speed connectors. Analysis is required to choose between the various alternatives and the platforms that enable them. One measure of performance of any alternative is the time it takes to close troops to the sea base or the time it takes to close to the sea base and deploy to objectives ashore. Closure time will also depend on whether a warning order was issued prior to the deployment order. One could assume that the decision to establish a sea base to support expeditionary maneuver warfare did not come as a surprise and that an alert order and warning order were issued sufficiently early to allow the troops, aircraft, and ships to be ready to go on receipt of the deployment order without delay. If this is not the case, then a preparation time prior to movement may be specified. JELO allows the user to specify preparation times.

6. Transfer from Connector to MPF(F)

Two of the possibilities for closing forces to the sea base require the transfer of the troops transported by the HSC or the RSLs to the MPF(F) ships at sea. As already noted, we

are uninformed as to the nature of this transfer operation. While it may be possible to accomplish this troop transfer with the use of a causeway, such an option would surely be sea state limited. Using a span wire and six-person transfer box yields a transfer rate of perhaps 90 troops per hour and is also likely sea state dependent [9]. A safer and more robust means of transfer is to airlift the troops from the HSC or RSLs to the MPF(F) using available aircraft. If the MV-22 aircraft self-deploy to the MPF(F) ships, they should be able to arrive within five days no matter the location of the sea base [7].

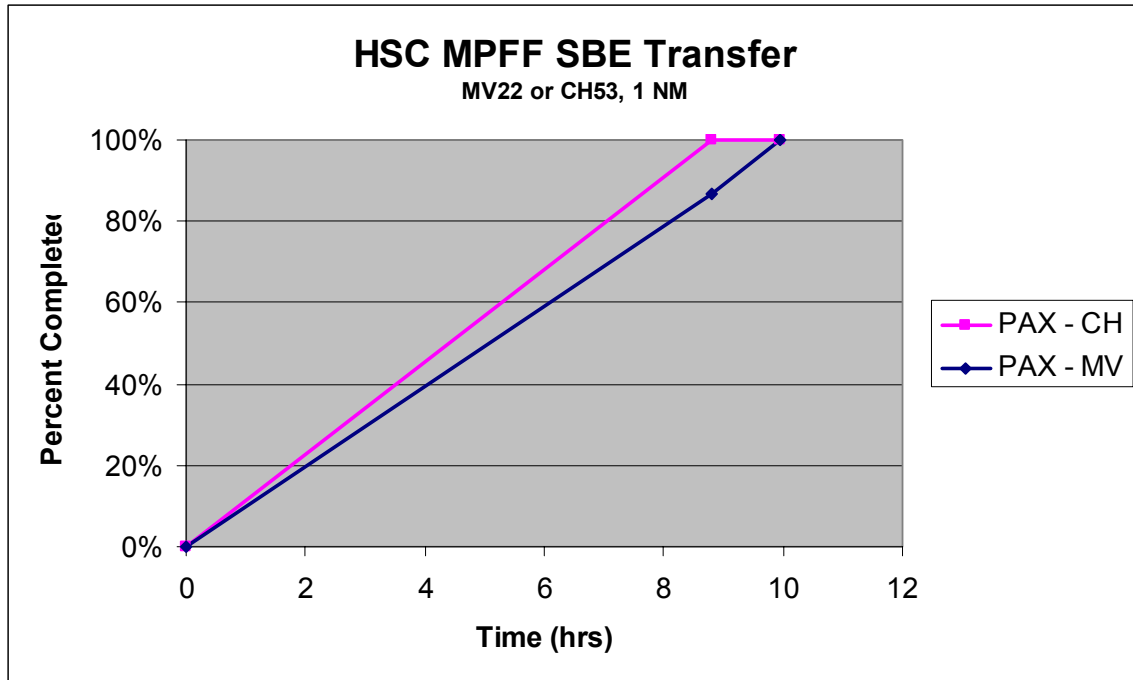

In order to see how long this transfer takes, something has to be assumed about the HSC or RSLs. The HSC is assumed to be something other than the HSV catamaran. What is known is that the HSC is a ship capable of at least 40 kts speed, configured to embark battalion-sized units, and potentially capable of operating tiltrotor aircraft [2]. The assumption in the example transfer below is that there are eight HSC vessels, each carrying 1,100 troops and having one aircraft operating spot. Alternatively, there might be four RSLs, each carrying 2,200 Marines and having two aircraft operating spots.

JELO's movement model, explained in Section 8, is used to estimate how long such a transfer will take. This is a simple operation with a single connector (MV-22), a single commodity to be transferred (troops), and a very short distance. Planning factors for MV-22 troop transfers are taken from [4]. Assuming 24 troops per trip, loading time is taken to be ten minutes, lift and clear is two minutes, approach and land is two minutes, and offload of troops is five minutes. If the distance between the sending and receiving ships is small, say 1,000 yards, flight time is negligible and assumed included in the clear and approach operations. The movement model result is that it will take 9.95 hours to complete troop transfer to the MPF(F) using 14 MV-22s, which cumulatively use 139.3 hours of the 384 available assuming an eight-hour crew-day. Also presented is the time for CH53s to accomplish the same task—8.79 hours with 13 helos, should they have reached the MPF(F) in time to perform this task.

HSC MPFF PAX transfer at 1 NM / 48 MV22 or 20 CH53 / 8 Loading Spots								
Loads	Start Total	Start Time	End Time	End Total	Spot #'s	Connector	# of connectors	Crew Day Used
PAX	8062	0	9.95	0	1,2,3, ... 8	MV	14	139.3
PAX	8062	0	8.79	0	1,2,3, ... 8	CH	13	114.27

Time	PAX - MV	PAX - CH
0	0	0
8.79	7003	8062
9.95	8062	8062

Crew Day Used	# units	hrs/unit	Total hrs	Used
CH	20	8	160	114.27
MV	48	8	384	139.3
LCAC	20	12	240	0

7. Assembly

Assembly is the selective breakout of the unit equipment and combat stores by the troops who will utilize both once deployed ashore. The operational status of the unit equipment (vehicles, weapons) must be determined and the equipment and stores on the MPF(F) staged for the deployment operation. The length of time needed depends on the status of the equipment and the physical characteristics of the MPF(F) ships. Assembly is not modeled. The goal for assembly is 24-48 hours [6], and the model has this as an input parameter.

8. Deploying the Maneuver Elements to Objectives Ashore

The seabased maneuver element of the MEB consists of three reinforced infantry battalions and associated direct support. As already noted, there is a lighter battalion that is to be deployed vertically (airlifted from the MPF(F) to the shore objective area), and two heavier mechanized battalions that are to be deployed by surface means; implicitly the beach is the initial objective area. Vertical deployment will utilize MV-22 and CH-53X aircraft. Surface deployment will utilize the EFV and LCAC craft. Both vertical and surface deployments involving moving troops, equipment, and two days of supply (DOS) of combat stores from the MPF(F) ships to objective areas ashore. The draft Sea Basing Concept of Operations [6] says there must be a minimum of supplies held ashore, no more than 2-4 days of supply. The daily resupply requirement is one day of supply, no matter the days of supply maintained ashore, but the safety level increases with the number of days of supply maintained ashore.

8.1 Deployment of the Vertical Battalion

The battalion to be vertically deployed consists of 1,164 troops whose major equipment includes 28 LAVs, eight EFSSs, and 143 HMMWVs variants [10]. The troops will be transported by MV-22s and MV-22s will also be involved in transporting the lighter vehicles. The heavier systems will be lifted by the CH-53X helicopter. The assumption is that 48 MV-22s and 20 CH-53Xs are available in the MPF(F) squadron [3], [10]. The length of time the vertical deployment requires will depend on the numbers to be lifted, the number of aircraft available, and the number of trips each aircraft can make to the required distance. The distance to the landing zone for the Vertical battalion is specified as 110 nm [10]. In the movement model, the distance from the MPF(F) to the landing zone of the Vertical battalion is an input parameter.

The term “trips” is used instead of sortie. For fixed wing aircraft, a sortie begins with a mission briefing, then engine start, flight, landing, engine shutdown, and debrief. This term is less useful for rotary wing or tiltrotor aircraft whose day’s activities may consist of a briefing, engine start, load, fly out, unload, fly back, load again, fly out again, etc., with hot refueling as required. This sort of activity is best described in terms of the number of trips.

The MV-22 tiltrotor aircraft will be the most numerous aircraft on the MPF(F) ships. They self-deploy to the MPF(F) ships for CONUS locations and can do this in five days or less to anywhere in the world [7]. The MV-22 can transport 24 troops internally and the speed is assumed to be 240 kts. With external load (either a vehicle, a sling of cargo pallets, or fuel bladders) speed is limited to 100 kts. Speed with external load is limited by the characteristics of the load rather than the aircraft lifting it. Maximum external load weight is 10,000 pounds and may be carried a distance of 110 nm. The other asset for vertical deployment is the CH-53X, a program of record. The CH-53X is to be a new airframe CH-53E with upgraded engines, blades, transmission, and avionics. The CH-53X will lift 6,700 pounds more than the 53E over the same distances as the 53E [11]. Vehicles weighing more than the 10,000-pound lift capacity of the MV-22 will be flown by CH-53X aircraft. Its speed with external load is 100 kts and its speed clean is 130 kts.

The movement model used to determine the time required to deploy the battalion calculates the productivity at each aircraft operational spot and then applies that to the number of units to be deployed [12]. This cannot be totally automated because there are two types of connectors (MV-22 and CH-53X), and troops, equipment, and stores to be deployed. There is a need to have a deployment plan that specifies the pairings between cargos and aircraft and the order in which the various commodities will be deployed. The movement model noted in Section 6 and resident in the spreadsheet is used to produce battalion deployment times that depend on the deployment plan, number of connectors available, number of operational spots available, and distance to which the commodities are to be flown. The user should evaluate one or several deployment plans and import the results of the better plan into the main part of the JELO model.

As an example of a deployment plan and use of the movement model, deployment of the Vertical battalion begins with the assignment of MV-22 aircraft to the lifting of the 1,164 troops to the landing zone 110 nm distant using two of the assumed four operating spots available (one spot per ship and four ships with the troops and equipment of the Vertical battalion; alternatively, the battalion on two ships and each ship has two spots). In order to avoid queuing of aircraft assets, only 12 of the available 48 are assigned. Simultaneously, on spot number 3, 16 of the 20 CH-53Xs start lifting the battalion's 28 LAVs, 8 EFSSs, and pallets while on spot number 4, 13 other MV-22s begin lifting the battalion's 143 HMMWVs. The troops are deployed in 6.44 hours and at that time spots 1 and 2, along with spot 4 are utilized by MV-22s to move HMMWVs. The CH-53Xs finish lifting the 36 LAVs/EFSSs and the pallets and bladders representing two DOS of provisions, water, fuel, and ammo at 10.23 hours, after which all four spots have MV-22s moving HMMWVs. This deployment plan results in the deployment of the Vertical battalion in 12.36 hours and utilizes 342 of the 384 MV-22 crew-day hours available and 147 of the 160 CH-53X crew-day hours available. Details of the application of the movement model to the deployment plan are presented in the spreadsheet display. Think of this estimated deployment time as "representative" only, as the actual deployment plan will surely be different in detail.

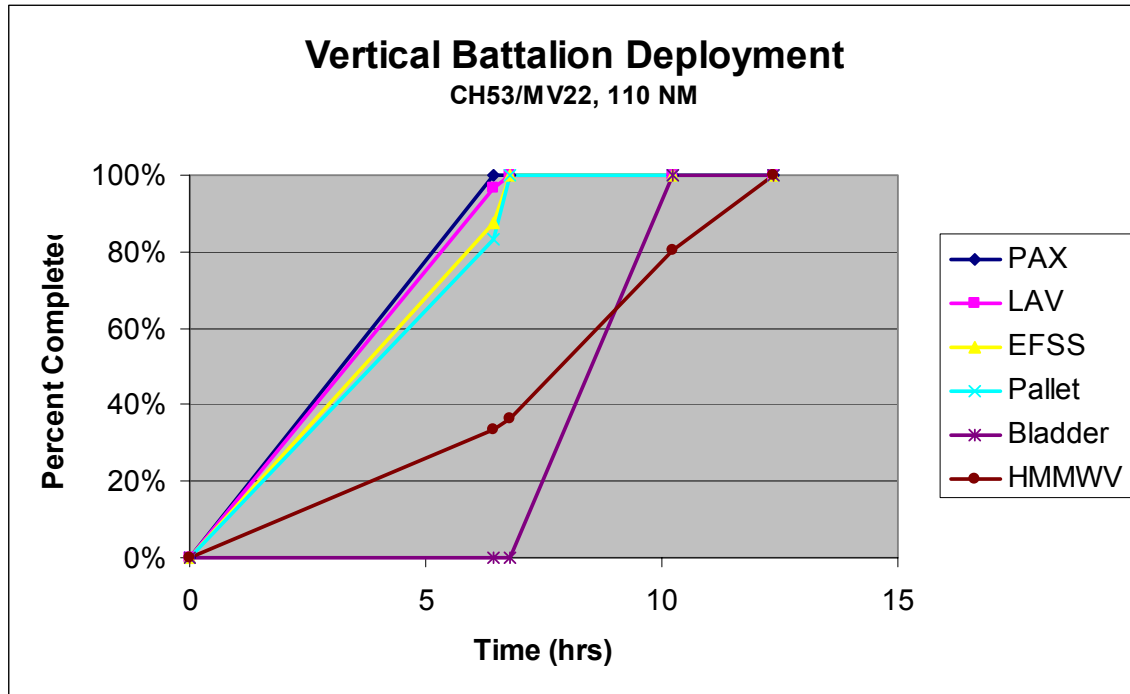

The movement model takes inputs such as the types and numbers of units to be moved, the distance, the number of spots, and the types and numbers of connectors, and computes the movement times and displays them in the following tables and graph.

Vertical Battalion at 110 NM / 48 MV22 / 20 CH53

Loads	Start Total	Start Time	End Time	End Total	Spot #'s	Connector	# of connectors	Crew Day Used

MV	48	8	384	341.92

8.2 Deployment of the Surface Battalions

There are two mechanized battalions that are to be surface deployed from 25 nm at sea to the shore with the beach as their initial objective. The deployment of the first Surface battalions is to begin simultaneously with the deployment of the Vertical battalion. As the vertical deployment uses almost all of the available aircraft crew-hours, the surface deployment operation is conducted by surface connectors (LCAC) exclusively. It is assumed the MPF(F) squadron will have 16-20 LCACs available for surface deployment and resupply [3]. The report of the Defense Science Board notes that the threat from Mach 3 sea-skimming missiles argues for keeping the ships of the sea base 100 miles from the shore [13]. However, connector limitations make this distance a most difficult prospect both in deployment operations and in resupply. The developing Sea Basing CONOPS assumes that during deployment MPF(F) ships will come to within 25 nm of the coast in consideration of LCAC delivery times, EFV transit times and fuel consumption, and aircraft deployment of forces to objectives inland from the coast. While operating at this distance from the coast, Sea Shield provided by combatants of the CSG and ESG must defend the sea base ships.

The surface-deployed battalions each consist of 1,840 troops with 53 EFVs, 14 M1A1 tanks, 28 LAVs, 6 LW155 artillery pieces, 6 HIMARSs, 157 HMMWV variants, 45 MTRVs, and 18 LVSs [10]. The 53 EFVs self-deploy from the MPF(F) ships to the shore with 20 Marines per vehicle (3 crew and 17 pax). This deployment carries 1,060 of the 1,840 troops to the shore. The other 780 troops are carried by LCACs while they deploy the battalion's vehicles and stores. The vehicles/weapon systems to be deployed include HMMWVs, LAVs, M1A1 tanks, MTRVs, HIMARS,

LVSSs, and light-weight 155mm howitzers. Each vehicle/weapon system has its own load and unload times, and number the LCAC can transport in a single trip, necessitating use of the transfer model separately for each.

The movement model is a circulation model used to calculate time required to deploy material and personnel considering loads, connectors, loading spots, and distance as major parameters. The model was used in connection with transferring troops from the HSC or RSLs to the MPF(F) ships in Section 6 and with the deployment of the Vertical battalion in Section 8.1 as well, but a full explanation is given here.

The JELO movement model is based on a fundamental calculation of connector cycle time as proposed by Keith McAllister in [12]. Below is a screenshot of the complete JELO movement model implemented in an Excel spreadsheet.

Movement Model							
Problem parameters							
Number of Cargo/Pax (total units)	157	No queuing due to spots					
Number of Connectors (total units)	20						
Number of Loading Spots	4						
One-way distance to objective (NM)	25						
Sea State	0						
Load Type	HMMWV						
Connector Type	LCAC						
Calculated/Look-up Factors							
Equivalent factor (McAllister)	2

As an example of the movement model, the following computations and Excel screenshots illustrate the cycle time calculation per [12] and JELO modifications to account for surge operations and minimum achievable movement times.

Suppose the requirement is transfer of 157 HMMWVs 25 nm to the ashore objective using as many as 20 LCACs and 4 loading spots with Sea State 0. Parameters are entered as shown—the first four values may be entered directly into their cell, or may be manipulated by the associated scroll bar; Sea State, Load, and Connector Type are entered into their cells with data validation checks to limit the model choices.

Problem parameters	
Number of Cargo/Pax (total units)	157
Number of Connectors (total units)	20
Number of Loading Spots	4
One-way distance to objective (NM)	25
Sea State	0
Load Type	HMMWV
Connector Type	LCAC

Next, a number of parameter values are set. For example, each load type is assigned characteristics for load and discharge rates. Rates are entered as minutes per unit of load; for example, HMMWVs are loaded to various connectors at a rate of four minutes per vehicle loaded and discharged at a rate of two minutes per vehicle unloaded.

Load Type	Load Rate	Discharge Rate
Bladder	4	2
CH 53	120	60
EFSS	4	2
HIMAR	4	2
HMMWV	4	2
LAV	4	2
LVS	4	2
LW155	4	2
M1A1	8	4
MTVR	4	2
PAX_fast	0.208	0.104
PAX_slow	0.417	0.208

Connector capacities, with respect to load types, are contained in a feasibility matrix. In this table, load types are cross-walked to specific connector configurations. In this instance, either CH-53s or MV-22s externally carry one HMMWV per lift, or LCACs transport 12 HMMWVs per lift.

Load Type	Capacity (units)							
	C 17	CH53_external	CH53_internal	EFV	LCAC	MV22_external	MV22_internal	
Bladder	0	2	0	0	0	8	2	0
CH_53	1	0	0	0	0	0	0	0
EFSS	0	1	0	0	0	4	0	0
HIMAR	0	1	0	0	0	4	0	0
HMMWV	0	1	0	0	0	12	1	0
LAV	0	1	0	0	0	4	0	0
LVS	0	0	0	0	0	2	0	0
LW155	0	1	0	0	0	4	0	0
M1A1	1	0	0	0	0	1	0	0
MTVR	0	0	0	0	0	3	0	0
PAX_fast	102	0	55	20	24	0	24	0
PAX_slow	102	0	55	20	24	0	24	0

Ingress and egress speeds are assigned by connector configuration, as are approach and clearing times. In this example, an LCAC has ingress and egress speeds of 40 kts, a four-minute approach time, and a two-minute clearing time. The Sea State parameter in the JELO movement model is used to impose degraded surface craft speeds in higher Sea States.

ConnectorType	Eq. Factor	Ingress Speed (kts)	Egress Speed (kts)	Time approach (min)	Time to Clear (min)
C 17	2	540	540	5	5
CH53 external	3	100	130	2	2
CH53 internal	3	130	130	2	2
EFV	2	25	25	2	2
LCAC	2	40	40	4	2
MV22 external	3	100	240	2	2
MV22 internal	3	240	240	2	2

LCAC Speed	
Sea State	Speed (kts)
0	40
1	40
2	35
3	30
4	25
5	0

Load (T_L) and Offload (T_O) times are a result of approach and clearing times and loading or discharge rates multiplied by the number of load units per lift. Cycle time (T_C) is calculated as the sum of load, offload, ingress, and egress times. In the table below, we see an example of LCAC transport of HMMWVs for a distance of 25 nm with $T_C = 2.65$ hrs, $T_L = 0.90$ hrs, and $T_O = 0.50$ hrs.

Calculated/Look-up Factors			
Equivalent factor (McAllister)	2		
eq # of connectors (McAllister)	10.0		minutes
Time per cycle (hrs) (T_c)	2.65		159
Load time (hrs) (T_L)		0.900	54.00
Offload Time (hrs) (T_O)		0.500	30.00
Ingress transit time (hrs) (T_{in})		0.625	37.5
Egress transit time (hrs) (T_{out})		0.625	37.5
	Time to approach/moor (T_a/m)	4	
	load rate (min/unit) (R)	4.000	
	discharge rate (min/veh) (Rd)	2.000	
	cargo/load units per lift (nv)	12	
	Time to cast-off/clear (T_c/c)	2	

A series of intermediate calculations are performed to determine the maximum number of connectors per loading spot and throughput rates—which are then applied to the total requirement to calculate the time for movement completion.

Problem parameters	
Number of Cargo/Pax (total units)	157

2.94	Connectors per spot (no queue)
141.3	Throughput per cycle (all con/spots)
53.3	Throughput per hour
2.94	Cargo/PAX divided by throughput
4.73	Time to complete (JELO MM)

Specific calculation details are described below.

Per [12], to calculate the round-trip cycle time (T_C) for LCACs:

$$T_C = \text{load time } (T_L) + 2 \times \text{one-way transit time } (T_T) + \text{offload time } (T_O)$$

We modify this calculation in the JELO movement model by allowing different ingress/egress transit speeds, so that:

$$T_C = T_L + \text{ingress time } (T_{IN}) + \text{egress time } (T_{OUT}) + T_O$$

Where:

$$T_L \text{ or } T_O = T_{A/M} + (R \times n_V) + T_{C/C}$$

With:

$T_{A/M}$ = time to approach and moor

R = load or discharge rate (min per unit of load)

n_V = units of load per connector lift

$T_{C/C}$ = time to cast-off/take-off and clear

So:

$$\begin{aligned} T_L &= T_{A/M} + (R \times n_V) + T_{C/C} \\ &= 4 \text{ min} + [(4 \text{ min/vehicle}) \times (12 \text{ vehicles})] + 2 \text{ min} \\ &= 54 \text{ min} = 0.90 \text{ hrs} \end{aligned}$$

$$\begin{aligned} T_O &= T_{A/M} + (R \times n_V) + T_{C/C} \\ &= 4 \text{ min} + [(2 \text{ min/vehicle}) \times (12 \text{ vehicles})] + 2 \text{ min} \\ &= 30 \text{ min} = 0.50 \text{ hrs} \end{aligned}$$

Calculated/Look-up Factors			
Equivalent factor (McAllister)	2		
eq # of connectors (McAllister)	10.0		
Time per cycle (hrs) (T_C)	2.65		
Load time (hrs) (T_L)		0.900	54.00
Offload Time (hrs) (T_O)		0.500	30.00
Ingress transit time (hrs) (T_{in})		0.625	37.5
Egress transit time (hrs) (T_{out})		0.625	37.5
	Time to approach/moor ($T_{a/m}$)	4	
	load rate (min/unit) (R_L)	4.000	
	discharge rate (min/veh) (R_d)	2.000	
	cargo/load units per lift (n_V)	12	
	Time to cast-off/clear ($T_{c/c}$)	2	

The time for the ingress trip from 25 nm will be:

$$T_{IN} = \frac{D}{V}$$

Where: D = distance, V = velocity

So:

$$T_{IN} = \frac{25 \text{ nm}}{40 \text{ kts}}$$

$$= 0.63 \text{ hrs or } 37.5 \text{ min}$$

Calculated/Look-up Factors			
Equivalent factor (McAllister)	2		
eq # of connectors (McAllister)	10.0		
Time per cycle (hrs) (Tc)	2.65		
Load time (hrs) (Tl)		0.900	
Offload Time (hrs) (To)		0.500	
Ingress transit time (hrs) (Tin)		0.625	
Egress transit time (hrs) (Tout)		0.625	
	Time to approach/moor (Ta/m)		4
	load rate (min/unit) (Rl)		4.000
	discharge rate (min/veh) (Rd)		2.000
	cargo/load units per lift (nv)		12
	Time to cast-off/clear (Tc/c)		2

minutes

159

54.00

30.00

37.5

37.5

In this case, $T_{IN} = T_{OUT}$, so:

$$T_C = T_L + T_{IN} + T_{OUT} + T_O$$

$$= 54 \text{ min} + 37.5 \text{ min} + 37.5 \text{ min} + 30 \text{ min}$$

$$= 159 \text{ min or } 2.65 \text{ hrs}$$

Calculated/Look-up Factors			
Equivalent factor (McAllister)	2		
eq # of connectors (McAllister)	10.0		
Time per cycle (hrs) (Tc)	2.65		
Load time (hrs) (Tl)		0.900	
Offload Time (hrs) (To)		0.500	
Ingress transit time (hrs) (Tin)		0.625	
Egress transit time (hrs) (Tout)		0.625	
	Time to approach/moor (Ta/m)		4
	load rate (min/unit) (Rl)		4.000
	discharge rate (min/veh) (Rd)		2.000
	cargo/load units per lift (nv)		12
	Time to cast-off/clear (Tc/c)		2

minutes

159

54.00

30.00

37.5

37.5

To calculate the number of connectors required to utilize fully one loading spot:

$$N_{\text{CONNMAX}} = \frac{T_C}{T_L}$$

$$= \frac{159 \text{ min}}{54 \text{ min}}$$

$$= 2.94 \text{ LCACs are required to utilize fully one loading spot}$$

2.94	Connectors per spot (no queue)
141.3	Throughput per cycle (all con/spots)
53.3	Throughput per hour
2.94	Cargo/PAX divided by throughput
4.73	Time to complete (JELO MM)

Note that this value also represents the maximum number of connectors that we would plan for any loading spot to prevent intentional queuing (that is, queuing caused by an oversupply of connector assets with respect to the cycle time/loading time ratio at a particular loading spot).

Connectors per spot ($\text{CONN}_{\text{SPOT}}$) is the minimum of:

- 1) McAllister's fully utilized spot (N_{CONNMAX}) and,
- 2) the ratio of number of connectors (N_{CONN}) to number of loading spots (N_{SPOTS}).

$$\text{CONN}_{\text{SPOT}} = \min (N_{\text{CONNMAX}}, (N_{\text{CONN}}/N_{\text{SPOTS}}))$$

$$= \min (2.94, 20/4)$$

$$= 2.94$$

Number of Connectors (total units)	20	◀	▶
Number of Loading Spots	4	◀	▶

Connectors per spot (McAllister, fully utilized, no queue)	2.944	2.94	Connectors per spot (no queue)
--	-------	------	--------------------------------

This ensures that we do not calculate a lift capability per spot that is greater than the physical assets we have assigned. McAllister's model assumes full utilization per spot, while the JELO movement model uses N_{CONNMAX} as an upper bound and allows partial utilization of a loading spot.

Throughput per cycle ($THRU_{CYC}$) is the product of the number of loading spots (N_{SPOTS}), units of cargo per connector lift (n_V), and Connectors per spot ($CONN_{SPOT}$).

$$\begin{aligned}
 THRU_{CYC} &= (N_{SPOTS}) (n_V) (CONN_{SPOT}) \\
 &= (4 \text{ spots/cycle}) (12 \text{ HMMWVs/LCAC}) (2.94 \text{ LCACs/Spot}) \\
 &= 141.3 \text{ HMMWVs per cycle}
 \end{aligned}$$

2.94	Connectors per spot (no queue)
141.3	Throughput per cycle (all con/spots)
53.3	Throughput per hour
2.94	Cargo/PAX divided by throughput
4.73	Time to complete (JELO MM)

Throughput per hour ($THRU_{HR}$) is the throughput per cycle ($THRU_{CYC}$) divided by the Time per cycle (T_C). In this example:

$$\begin{aligned}
 THRU_{HR} &= \frac{THRU_{CYC}}{T_C} \\
 &= \frac{141.3 \text{ HMMWVs/cycle}}{2.65 \text{ hrs/cycle}} \\
 &= 53.3 \text{ HMMWVs per hr}
 \end{aligned}$$

Finally, the time to complete the offload (T_{TOTAL})—that is, the HMMWVs arrive at the ashore objective—is the maximum of:

- 1) the total cargo movement requirement (N_{CARGO}) divided by the hourly throughput ($THRU_{HR}$) and
- 2) the sum of the running time for all loading evolutions, plus the ingress time (T_{IN}), plus the offload time (T_O).

The sum of the running time for all loading evolutions is calculated as the Time to load (T_L) multiplied by the maximum whole number of concurrent loading evolutions that must take place—that is, the ceiling (or round-up to the next integer) of N_{CARGO} divided by the product of the minimum of the number of connectors (N_{CONN}) or number of loading spots (N_{SPOTS}) and number of units lifted per connector load (n_V). Specifically:

$$T_{TOTAL} = \max \left\{ \left(\frac{N_{CARGO}}{THRU_{HR}} \right), \sum \left[\left(T_L \times \text{Ceiling} \left(\frac{N_{CARGO}}{\left(\min(N_{CONN}, N_{SPOTS}) \times n_V \right)} \right) \right) \right], T_{IN}, T_O \right\}$$

$$= \max \{(157/53.3), \sum [(0.9) \times \text{Ceiling} (157/(\min(20, 4) \times 12))], 0.5, 0.625\}$$

$$= \max (2.95, 4.73) = 4.73 \text{ hrs to complete the HMMWV offload}$$

Connectors per spot (McAllister, fully utilized, no queue)	2.944	2.94	Connectors per spot (no queue)
Spots required/provided	3.396	141.3	Throughput per cycle (all con/spots)
Load offloaded loading cycle	40.755	53.3	Throughput per hour
Productivity (load/min)	0.755		
Time to complete offload (hrs) given 4 spots (McAllister)	3.47	2.94	Cargo/PAX divided by throughput
		4.73	Time to complete (JELO MM)

It should be noted that the same result can be accomplished with far fewer assets—that is, a 4.73-hour completion with fewer than 20 LCACs. Since we had calculated a maximum of 2.94 connectors per spot to avoid queuing, and we currently employ five LCACs per spot (20 LCACs divided by four spots), we should be able to decrease the total number of LCACs and achieve the same completion time. This is the case, as pictured below, where 12 LCACs are using four loading spots.

Problem parameters			
Number of Cargo/Pax (total units)	157		
Number of Connectors (total units)	12		
Number of Loading Spots	4

		4.73	Time to complete (JELO MM)

This example detailed the calculations necessary for a single Load and Connector Type. There is a governing requirement to have a deployment plan that specifies the pairings between cargos and connectors and the order in which the various commodities will be deployed. The plan presented makes trade-offs among the connector assets and load types to achieve an overall timeline that is less than a simple serial deployment time, which sequentially focuses on individual load types. Prudent tactical employment likely argues against offloading load types serially, however, these tactical considerations have not been fully explored, and the calculations presented in this report should be considered reasonable surrogates for the detailed deployment plan that would be executed.

As an example of a full deployment plan using the movement model, envision deployment of a Surface battalion (see table below). Deployment begins with the assignment of 53 EFVs to transporting 1,060 troops to a landing zone 25 nm distant using all four of the assumed loading spots available (one spot per ship and four ships with the troops and equipment of the Surface battalion; alternatively, the battalion on 2 ships and each ship has two spots). There is no circulation of these EFV assets, so the end time of 1.75 hours reflects queuing for departure from the Sea Base. Once the EFVs have cleared the loading spots, deployment of the other load types can begin. In order to avoid queuing of LCACs, only 15 of the available 20 are initially assigned. Simultaneously, on spot numbers 1 and 2, ten of the 20 LCACs start lifting the battalion's 14 M1A1s, while on spot numbers 3 and 4, five of the 20 LCACs start lifting the battalion's 157 HMMWVs.

Surface Battalion at 25 NM / 20 LCAC / 4 Loading Spots								
Loads	Start Total	Start Time	End Time	End Total	Spot #'s	Connector	# of connectors	Crew Day Used

10.89	1814	14	28	6	6	157	45	15
11.14	1840	14	28	6	6	157	45	18

Crew Day Used	# units	hrs/unit	Total hrs	Used
CH	20	8	160	0
MV	48	8	384	0
LCAC	20	12	240	126.73

Note: In the movement model detailed previously, we found that the minimum time for deployment of 157 HMMWVs was accomplished using four spots with as few as eight LCACs. We're now proposing use of only two loading spots, and the minimum time for the HMMWV deployment is achieved with only five LCACs. Thus, HMMWV deployment time is 7.43 hours (below) and reflected in the deployment plan (above) as the difference between 1.75 and 9.18 hours.

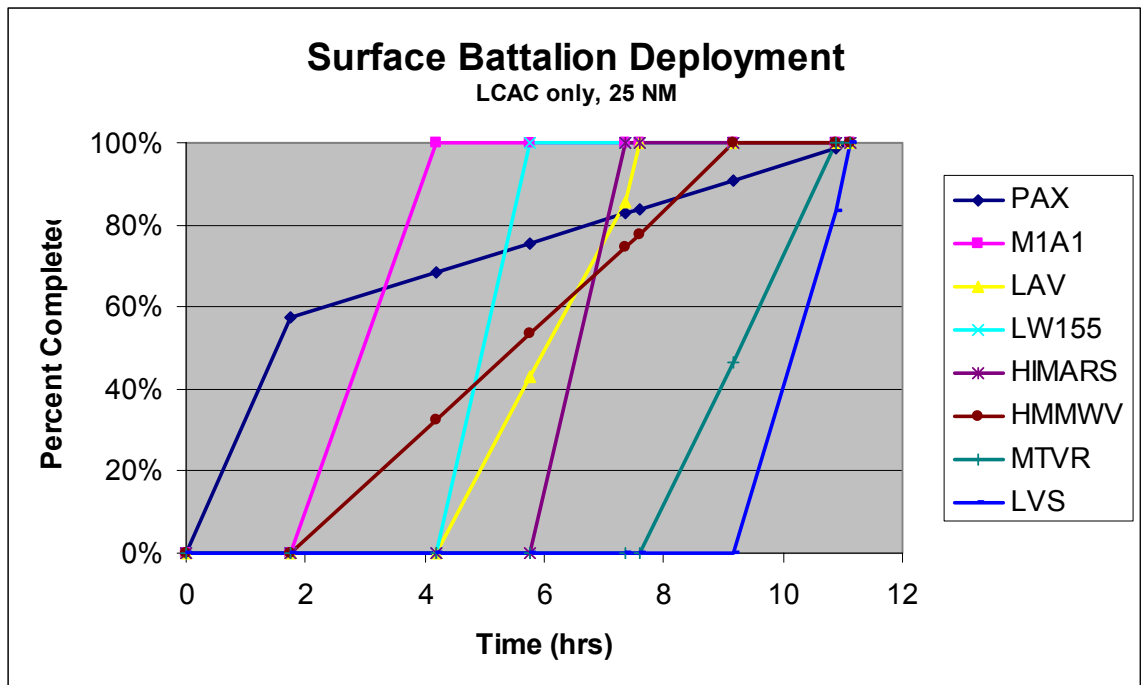

Problem parameters			
Number of Cargo/Pax (total units)	157		
Number of Connectors (total units)	5		
Number of Loading Spots	2		No queuing due to spots

Productivity (load/min)		0.189	22.6
Time to complete offload (hrs) given 1 spots (McAllister)	13.87	6.93	Throughput per hour
		7.43	Cargo/PAX divided by throughput
			Time to complete (JELO MM)

M1A1 deployment is complete at 4.18 hours, so LAV and LW155 deployments begin on loading spots 1 and 2 using four and two LCACs, respectively. HIMARS deployment begins on loading spot 2 at 5.77 hours. MTRV deployment begins at both spots 1 and 2 at 7.61 hours. HMMWV deployment is complete at 9.18 hours, so LVS deployment can begin on loading spots 3 and 4. The two DOS of combat stores are carried in tactically loaded vehicles as they are deployed from the MPF(F). This deployment plan results in the deployment of a Surface battalion in 11.14 hours and utilizes nearly 127 of the 240 LCAC crew-day hours available.

Surface Battalion at 25 NM / 20 LCAC / 4 Loading Spots

Decisions regarding how many loading spots and connectors to assign to each load type were made by considering the total numbers of loading spots and connectors available, the impact on crew-day used by the connectors, and the desirability for balanced arrival of load types to the objective. The table below details some of the trade-offs with regard to the Surface battalion movement. Highlighted rows are the selections made for the example detailed above.

Choices considered for number of LCACs and Spots per load					
Loads	Total req	LCACs	Spots	Time	Cr Day Use
M1A1	14	8	1	4.06	32.48
	14	10	2	2.43	24.3
	14	12	3	1.96	23.52

9. Illustrative Examples

To demonstrate the use of the JELO spreadsheet model, a few of the many possible ways of flowing expeditionary ground forces from CONUS to the sea base are explored as examples. The examples vary the methods and parameters of closing forces to the sea base. These examples use the transfer results from Section 6 if applicable, and the deployment results from Section 8.

The examples involve a few of the many possible combinations of rapid strategic lift ships, strategic airlift, and high speed connectors in accomplishing the closure of troops and non-self deploying aircraft (NSDA) to the sea base. Example 1 involves using strategic airlift and high speed connectors under various (four in total) assumptions regarding the timeliness and availability of strategic airlift aircraft. Example 2 involves using high speed rapid strategic lift ships to move troops and NSDA to the sea base without the requirement for strategic airlift or high speed connectors transiting between the advance base and the sea base. Example 3 involves either strategic airlift or rapid strategic lift ships transporting troops and NSDA to the advance base and being loaded onto the MPF(F) ships at the advance base thus eliminating the need for transfers at sea. The results of all seven examples are optimistic in the sense that they assume the issuance of a warning order sufficiently in advance of the deployment order that many of the

“preparation” delays may be avoided. The model accepts various preparation delays if this is not the case.

9.1 Example 1

In this example, and three variations on it, the troops of the Seabased Echelon plus the Naval Support Element (NSE) are flown by CRAF aircraft from CONUS to the advance base. At the advance base the troops transfer in port to HSC vessels for transport to the sea base. The number of HSCs and their passenger capacities are assumed to be sufficient to carry the full Seabased Echelon without making multiple roundtrips. It is assumed that the MV-22 self deploy from CONUS to the sea base. MPF(F) proceed direct to the sea base (see Figure 5).

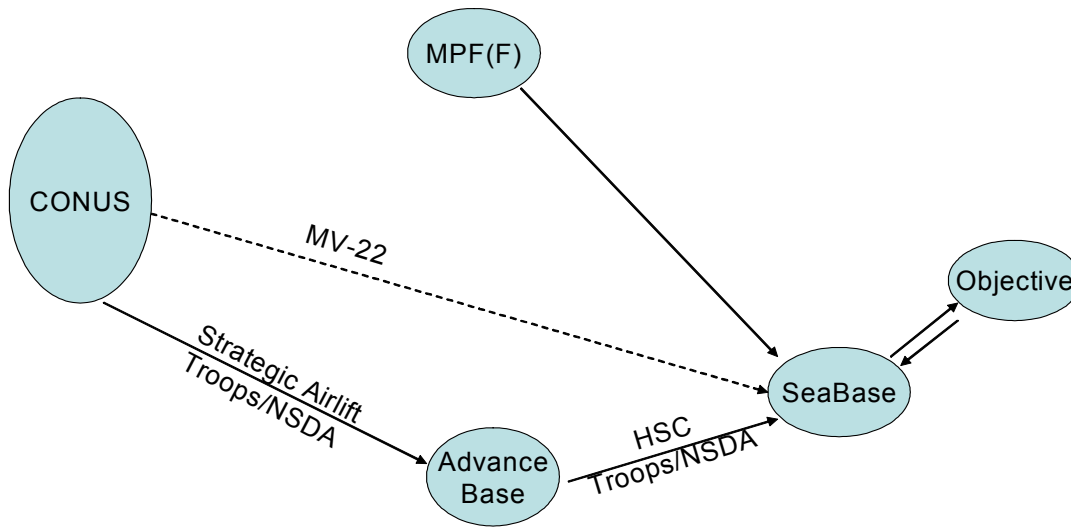

Figure 5. MPF(F) Direct to Sea Base, HSCs Utilized

Non-self-deploying aircraft (NSDA) are flown by strategic airlift to the advance base and sealifted onward to the MPF(F) ships at the sea base; details will be presented directly. Once the HSCs carrying the troops arrive at the sea base, the troops must be transferred to the MPF(F) ships.

This example was evaluated with the JELO Excel model (Figure 6) using notional parameter entries, resulting in troop closure at the ashore objective in 194.6 hours, or approximately 8.1 days. This is the most optimistic of the example results and assumes,

in addition to an early warning order being issued, that strategic airlift can begin with sufficient aircraft made available directly on issuance of the deployment order.

In general, all parameter values are user selectable—the color convention is:

Blue – values that are entered elsewhere in the spreadsheet and are simply referenced at the current cell.

Green – values that are directly entered at the current cell. Currently, some of these values have Data Validation to facilitate rational data entry.

Black – calculated values.

Light Yellow highlight (first column to the right of data parameters) – intermediate results that may be of interest.

Deep Yellow highlight (column furthest to the right) – output of interest.

Entries circled in Figure 6 will be discussed in detail below, along with an explanation of the logic used to calculate the model output.

1 MPFF Transit			
1.0 MPFF SeaState	0		
1.1 MPFF preparation time for underway (hrs)	0

3.8 Time to transfer Troops from HSC to SeaBase (hrs)	9.95		
3.9 SubOutput: Delay of HSC/Troops waiting for MPFF		0.0	
3.10 SubOutput: Time to move Troops from AB to MPFF ships (hrs)		72.0	
3.11 Output: Total time Deployment Order to Troops close MPFF at SeaBase (hrs)			91.1
3A Non-self deploying aircraft (NSDA) movement CONUS to AB/SeaBase			
3A.0 NSDA SeaState	0		
3A.1 Time to reposition NSDA at APOE in CONUS (hrs)	12		
3A.1.1 Time to assemble airlift	0		
3A.2 Time to disassemble NSDA for transport flight to AB (hrs)	36		
3A.3 SubOutput: Transport flight time CONUS APOE to AB (hrs)		11.1	
3A.3.1 NSDA Transport Distance (NM)	6000		
3A.3.2 NSDA Transport Speed (kts)	540		
3A.3.3 Airlift time by circulation model (hrs - compute offline)	0		
3A.4 SubOutput: Time for NSDA ready for onload HSC (hrs)		107.1	
3A.4.1 Reassembly time of NSDA at AB (hrs)	36		
3A.4.2 Flight test of NSDA at AB (hrs)	12		
3A.4.3 Preparation of NSDA for onload to HSC (hrs)	0		
3A.5 NSDA Delay at AB awaiting HSC (hrs)		0.0	
3A.5.1 Dedicated HSC available for NSDA?	Yes		
3A.6 NSDA onload to HSC	0		
3A.7 NSDA transit on HSC from AB to MPFF/SeaBase (hrs)		50.0	
3A.7.1 Distance (NM)	2000		
3A.7.2 HSC burdened speed (kts)	40		
3A.7.2.1 HSC NSDA Effective Speed	40.0		
3A.8 NSDA transfer from HSC to MPFF (hrs)	2		
3A.9 Output: NSDA close at SeaBase (hrs)			159.1
4 Assembly of Force Package			
4.1 Mating-up of Troops and unit equipment (hrs)	24		
4.2 Output: Time force package available for transport MPFF to shore (hrs)			115.1
4.3 SubOutput: Delay awaiting NSDA for forward movement (hrs)		44.1	
5 Deploy Force Package to Objectives Ashore			
5.0 Assault Package Deployment Time (hrs)			35.5
5.0.1 Vertical Battalion Deployment Times (hrs)	12.36		
5.0.2 First Surface Battalion Deployment Time (hrs)	11.14		
5.0.3 Operational Pause/Crew-Rest delay (hrs)	12		
5.0.4 Second Surface Battalion Deployment Time (hrs)	11.14		
5.1 Output: Time to put Troops at objective area - since deployment order (hrs)			194.6

Figure 6. JELO Excel Model, Example 1: MPF(F) Direct to Sea Base, HSCs Utilized

Several of the JELO time components are simple distance/speed calculations. The time for the MPF(F) to transit to the sea base is $1,800 \text{ nm}/24 \text{ kts} = 75.0$ hours. The three Blue entries are all entered on a common worksheet and are Global parameters—that is, they will be referenced by one, or more, of the possible closure models. Note that Sea State will impact effective speed for surface vessels—higher Sea States degrade speed. Except for the LCACs used in the movement ashore, we do not have valid data for the Sea State effect, but a placeholder model has been used to keep this computation capability in the JELO model.

1 MPFF Transit		
1.0 MPFF SeaState		0
1.1 MPFF preparation time for underway (hrs)		0
1.2 SubOutput: MPFF transit time to SeaBase (NM)		75.0
1.2.1 MPFF transit distance to SeaBase (NM)	1800	
1.2.2 MPFF transit speed (kts)	24	
1.2.2.1 MPFF Effective Speed	24.0	
1.3 Output: Time from deployment order to MPFF arrives SeaBase (hrs)		75.0

Other time components within JELO may be sequences of events that occur in series and/or parallel. The time for completion of the sequence is the sum of the individual events, with consideration for concurrent events. As an example of concurrent (or parallel) events, we model the sequential series “Troop Preparation for Overseas Movement (POM) and Transport time to the APOE” as occurring in parallel with the sequential series “Time to schedule airlift and Time for airlift to assemble at the APOE,” so only the maximum of these two serial times would count against the total for the entire sequence. Troop movement to the advance base is calculated as the sum of:

$$\text{MAX}(\text{Troop Preparation for Overseas Movement (POM)} + \text{Transport time to the APOE}, \\ \text{Time to schedule airlift} + \text{Time for airlift to assemble at the APOE}) \\ + \text{Time to load aboard the airlift} + \text{Time to fly to the advance base}$$

In this example, some of these times are assumed equal to 0 (zero) due to issuance of a warning order prior to an execution order. Note that troop closure to the advance base takes 19.1 hours.

2 Troop Movement to AB		
2.1 Troop POM delay at CONUS origin (hrs)		0
2.1.1 Number of troops for lift (pax)	8062	
2.2 Troops transported to APOE (hrs)	4	
2.3 Time to schedule airlift (hrs)	0	
2.4 Time sequence for airlift arrival/departure APOE (hrs)	0	
2.5 Time to load airlift at APOE (hrs)	4	
2.6 SubOutput: Time to fly CONUS to AB (hrs)		11.1
2.6.1 Distance APOE to AB (NM)	6000	
2.6.2 Speed APOE to AB (kts)	540	
2.7 Output: Time from deployment order until Troops arrive AB		19.1

After arriving at the advance base, the troops take time to deplane (eight hours) and then embark (four hours) on the HSCs. HSCs are assumed to be located at the advance base, though there is provision to calculate any delay that may be incurred if that were not the case. Travel to the sea base is again a distance/speed calculation ($2,000 \text{ nm}/40 \text{ kts} = 50$ hours). Transfer from the HSC to the MPF(F) was calculated as 9.95 hours using the JELO movement model and then was entered into this closure model. Troops close the sea base at 91.1 hours after the deployment execution order, or 3.8 days.

3 Troop Movement to MPFF Ships

3.0 HSC SeaState	0	
3.1 Troops deplane at AB, move to HSC (hrs)	8	
3.2 SubOutput: HSC time to AB (post deployment order) (hrs)	0	0.0
3.2.1 HSC distance to AB at deployment order (NM)	40	
3.2.2 HSC transit speed (kts)	40.0	
3.2.2.1 HSC unladen Effective Speed	40.0	0.0
3.3 SubOutput: Troop delay awaiting HSC (hrs)		
3.4 HSC parameters:		
3.4.1 Vessel capacity (pax)	1100	
3.4.2 Number of vessels (units)	8	
3.4.2.1 SubOutput: HSC shuttle required (Yes/No)	No	
3.5 Troop onboard to HSC (hrs)	4	
3.6 SubOutput: HSC Transit time AB to SeaBase (hrs)		50.0
3.6.1 HSC transit distance AB to SeaBase (NM)	2000	
3.6.2 HSC transit speed (kts)	40	
3.6.2.1 HSC burdened Effective Speed	40.0	
3.7 SubOutput: Time to move Troops from AB to SeaBase (hrs)		62.0
3.8 Time to transfer Troops from HSC to SeaBase (hrs)	9.95	
3.9 SubOutput: Delay of HSC/Troops waiting for MPFF		0.0
3.10 SubOutput: Time to move Troops from AB to MPFF ships (hrs)		72.0
3.11 Output: Total time Deployment Order to Troops close MPFF at SeaBase (hrs)		91.1

The non-self-deploying aircraft (NSDA) present a straightforward series of events related to movement by strategic airlift. Note that the delay in the availability of strategic airlift, data element 3A.1.1, is set to zero in this example. NSDA will take 48 hours to position and prepare for transport, then incur a distance/speed time for travel to the advance base, then must reassemble and conduct check flights (another 48 hours) for a total delay of 107.1 hours prior to loading aboard the HSC for lift to the sea base. Transit to the sea base is a simple distance/speed calculation, to which we add the flyoff transfer time and calculate a total time for NSDA sea base closure at 159.1 hours, or 6.6 days.

3A Non-self deploying aircraft (NSDA) movement CONUS to AB/SeaBase

3A.0 NSDA SeaState	0	
3A.1 Time to reposition NSDA at APOE in CONUS (hrs)	12	
3A.1.1 Time to assemble airlift	0	
3A.2 Time to disassemble NSDA for transport flight to AB (hrs)	36	
3A.3 SubOutput: Transport flight time CONUS APOE to AB (hrs)		11.1
3A.3.1 NSDA Transport Distance (NM)	6000	
3A.3.2 NSDA Transport Speed (kts)	540	
3A.3.3 Airlift time by circulation model (hrs - compute offline)	0	
3A.4 SubOutput: Time for NSDA ready for onboard HSC (hrs)		107.1
3A.4.1 Reassembly time of NSDA at AB (hrs)	36	
3A.4.2 Flight test of NSDA at AB (hrs)	12	
3A.4.3 Preparation of NSDA for onboard to HSC (hrs)	0	
3A.5 NSDA Delay at AB awaiting HSC (hrs)		0.0
3A.5.1 Dedicated HSC available for NSDA?	Yes	
3A.6 NSDA onboard to HSC	0	
3A.7 NSDA transit on HSC from AB to MPFF/SeaBase (hrs)		50.0
3A.7.1 Distance (NM)	2000	
3A.7.2 HSC burdened speed (kts)	40	
3A.7.2.1 HSC NSDA Effective Speed	40.0	
3A.8 NSDA transfer from HSC to MPFF (hrs)	2	
3A.9 Output: NSDA close at SeaBase (hrs)		159.1

Adding 24 hours, for mating-up with equipment, to the 91.1 required for Troop closure on the MPF(F), we calculate that the troops are ready for onward movement 115.1 hours (4.8 days) after the deployment order. However, we had just calculated that the NSDA would not arrive until 159.1 hours, so there is a delay of at least 44 hours waiting for the NSDA.

4 Assembly of Force Package

4.1 Mating-up of Troops and unit equipment (hrs)	24	
4.2 Output: Time force package available for transport MPFF to shore (hrs)		115.1
4.3 SubOutput: Delay awaiting NSDA for forward movement (hrs)		44.1

Finally, with all required elements having closed the sea base, onward movement to the ashore objectives can commence. As demonstrated in Section 8, the JELO movement model can be used to calculate deployment times for the Vertical- and Surface-deployed battalions. As before, this time is the sum of individual event times—in this case, the Vertical and first Surface battalions deploy simultaneously, so the maximum of those two is added to the operational pause (driven by limited connector assets) and deployment of the second Surface battalion for a total of 35.5 hours. Deployment closure is achieved at 194.6 hours, or 8.1 days.

5 Deploy Force Package to Objectives Ashore		
5.0	Assault Package Deployment Time (hrs)	35.5
5.0.1	Vertical Battalion Deployment Times (hrs)	12.36
5.0.2	First Surface Battalion Deployment Time (hrs)	11.14
5.0.3	Operational Pause/Crew-Rest delay (hrs)	12
5.0.4	Second Surface Battalion Deployment Time (hrs)	11.14
5.1	Output: Time to put Troops at objective area - since deployment order (hrs)	194.6

Example 1.1

Example 1 assumed both immediate and sufficient strategic airlift availability to move NSDA in a single wave from CONUS to the advance base without delay. If this is not the case, additional time for the deployment can be expected. In Example 1.1 there is a 96-hour delay to the start of flights transporting NSDA to the advance base. Note that data element 3A.1.1 in the spreadsheet screenshot that follows now has the value of 96 hours. The delay is perhaps the time needed to establish the air bridge from CONUS to the advance base. It is assumed, however, that once airlift begins (at C-day + 96 hours) aircraft are available in sufficient quantity for a single wave carrying 20 CH-53s. This example results in overall closure to the objective at 278.6 hours vice the 194.6 hours required in Example 1.

5.0.4 Second Surface Battalion Deployment Time (hrs)	11.14		
5.1 Output: Time to put Troops at objective area - since deployment order (hrs)			278.6

Example 1.2

In this example, NSDA strategic airlift for the 20 CH-53s is delayed 96 hours and, once it begins, is limited to four sorties per day. In this case, closure to the objective is achieved at 395.3 hours vice 194.6 hours. Note that the limited number of connectors, assumed to be C-17s in this example, is reflected in the JELO Movement Model. The output of the Movement Model is then transferred to the main spreadsheet; data element 3A.3.3.

Example 1.3

In this example, all the conditions of Example 1.2 persist, but it is recognized that in addition to the CH-53s, the MEB's 32 AH/UH tactical helos must also be transported by strategic airlift. These 32 additional helos require 8 additional strategic airlift sorties, and are reflected in the Movement Model. For this example, the ultimate closure time increased to 446.4 hours.

9.2 Example 2

In this example, rapid strategic lift ships (RSLs) on-load troops, NSDA, and non-repositionable cargo in CONUS and transit directly to the sea base. As in Example 1, the MPF(F) transit directly from their preposition site to the sea base. When both the RSLs and MPF(F) have arrived at the sea base, the troops transfer from the RSLs to the MPF(F) (see Figure 7).

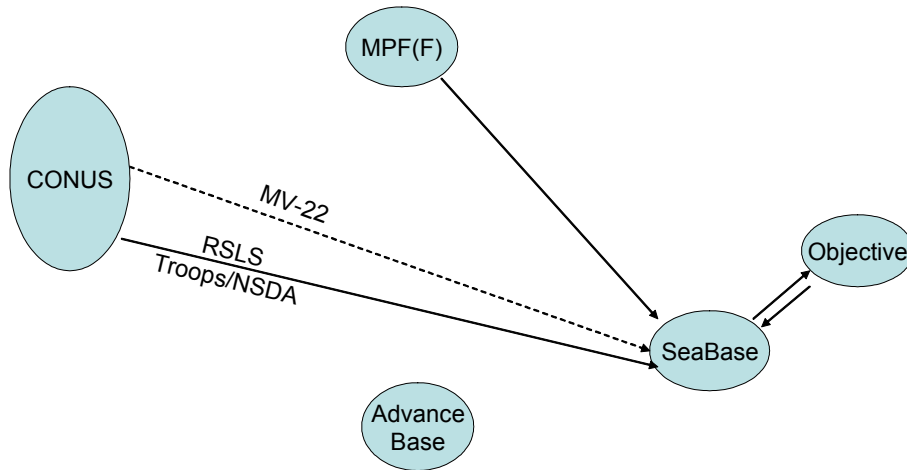

Figure 7. MPF(F) Direct to Sea Base, RSLSs Utilized

Output from the JELO Flow model for this example is shown in Figure 8. MPF(F) transit is identical to Example 1, again taking 75.0 hours to transit to the sea base. Troop and NSDA movement aboard the RSLSs follows logic similar to the strategic airlift of Example 1. Both troops and NSDA reposition and then load aboard the RSLSs, followed by a distance/speed calculation for the voyage to the sea base. The RSLSs close at the sea base after 193.0 hours (eight days), and then transfer of the troops to the MPF(F) occurs as described by the JELO movement model (Section 6) in 9.95 hours. After a 24-hour period to mate-up with equipment, the troops are ready for onward movement at 227 hours (9.5 days). Deployment takes place as previously described (Section 8) and closure occurs at 262.5 hours (10.9 days).

Figure 8. JELO Excel Model, Example 2: MPF(F) Direct to Sea Base, RSLs Utilized

9.3 Example 3

In this example, forces are still flown to the advance base, but the MPF(F) sails from its preposition site to the advance base and thus serves as the connector. The MPF(F) ships would then sail for the sea base as soon as the troops and cargo could be loaded at the advance base. NSDA would still be flown by strategic airlift to the advance base and made flight-ready there (see Figure 9). If they are able to arrive at the advance base within a designated waiting period, NSDA could be transported by MPF(F). If the NSDA arrive too late for the MPF(F), they could still be loaded when ready onto HSCs for transport to the sea base. Once within range of the sea base, these aircraft could launch and fly to the MPF(F) ships.

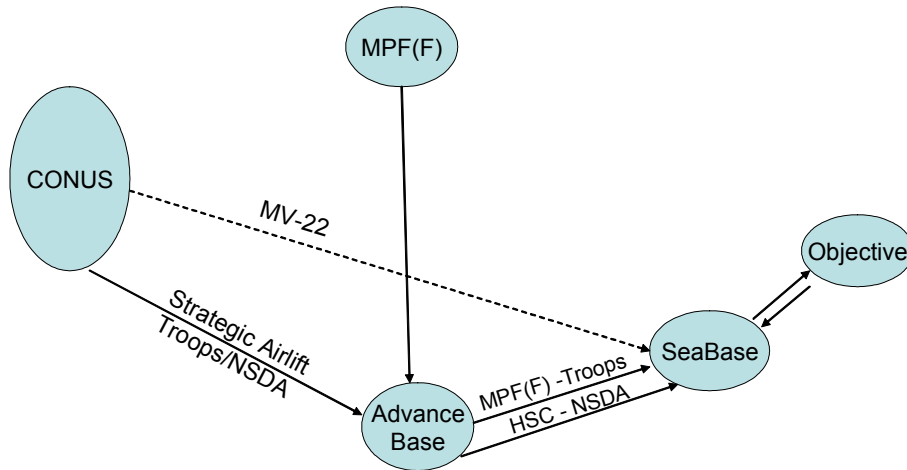

Figure 9. MPF(F) Calls at Advance Base En route to Sea Base

The JELO Flow model for Example 3 is shown in Figure 10. MPF(F) transit is a distance/speed event taking 83.3 hours to transit to the advance base (depending, of course, on user-specified MPF(F) transit speed and distance from preposition site to the advance base). Troop arrival at the advance base at 19.1 hours, plus their eight-hour delay to deplane and move to the MPF(F) loading point, still leaves a 56.2-hour delay awaiting the MPF(F) arrival. This observation argues for the MPF(F) and advance base to be collocated. A 20-hour window for NSDA has been modeled—since the actual delay calculates as 23.8 hours, the MPF(F) will sail without embarking the NSDA at the advance base. This max allowable waiting period is, of course, user selectable.

In this example it was again assumed that sufficient strategic airlift for the NSDA is available immediately after the deployment order is given—a most convenient circumstance. Nonetheless, the NSDA are not available for load aboard the MPF(F) until 107.1 hours, so the NSDA will be sealifted by HSC. Note that the HSC will arrive at the sea base at 159.1 hours, while the MPF(F) will not arrive until 170.7 hours. The HSC's greater speed (40 kts versus 24 kts for the MPF(F)) allows the quicker transit. In this case, it seems likely that the NSDA will fly aboard the MPF(F) prior to arrival at the sea base, though no explicit calculation is performed for that event. Since the troops went aboard the MPF(F) at the advance base, there is no mate-up time with equipment. Finally, deployment to the ashore objective proceeds as before, and results in a force closure to objective time of 206.2 hours (8.6 days).

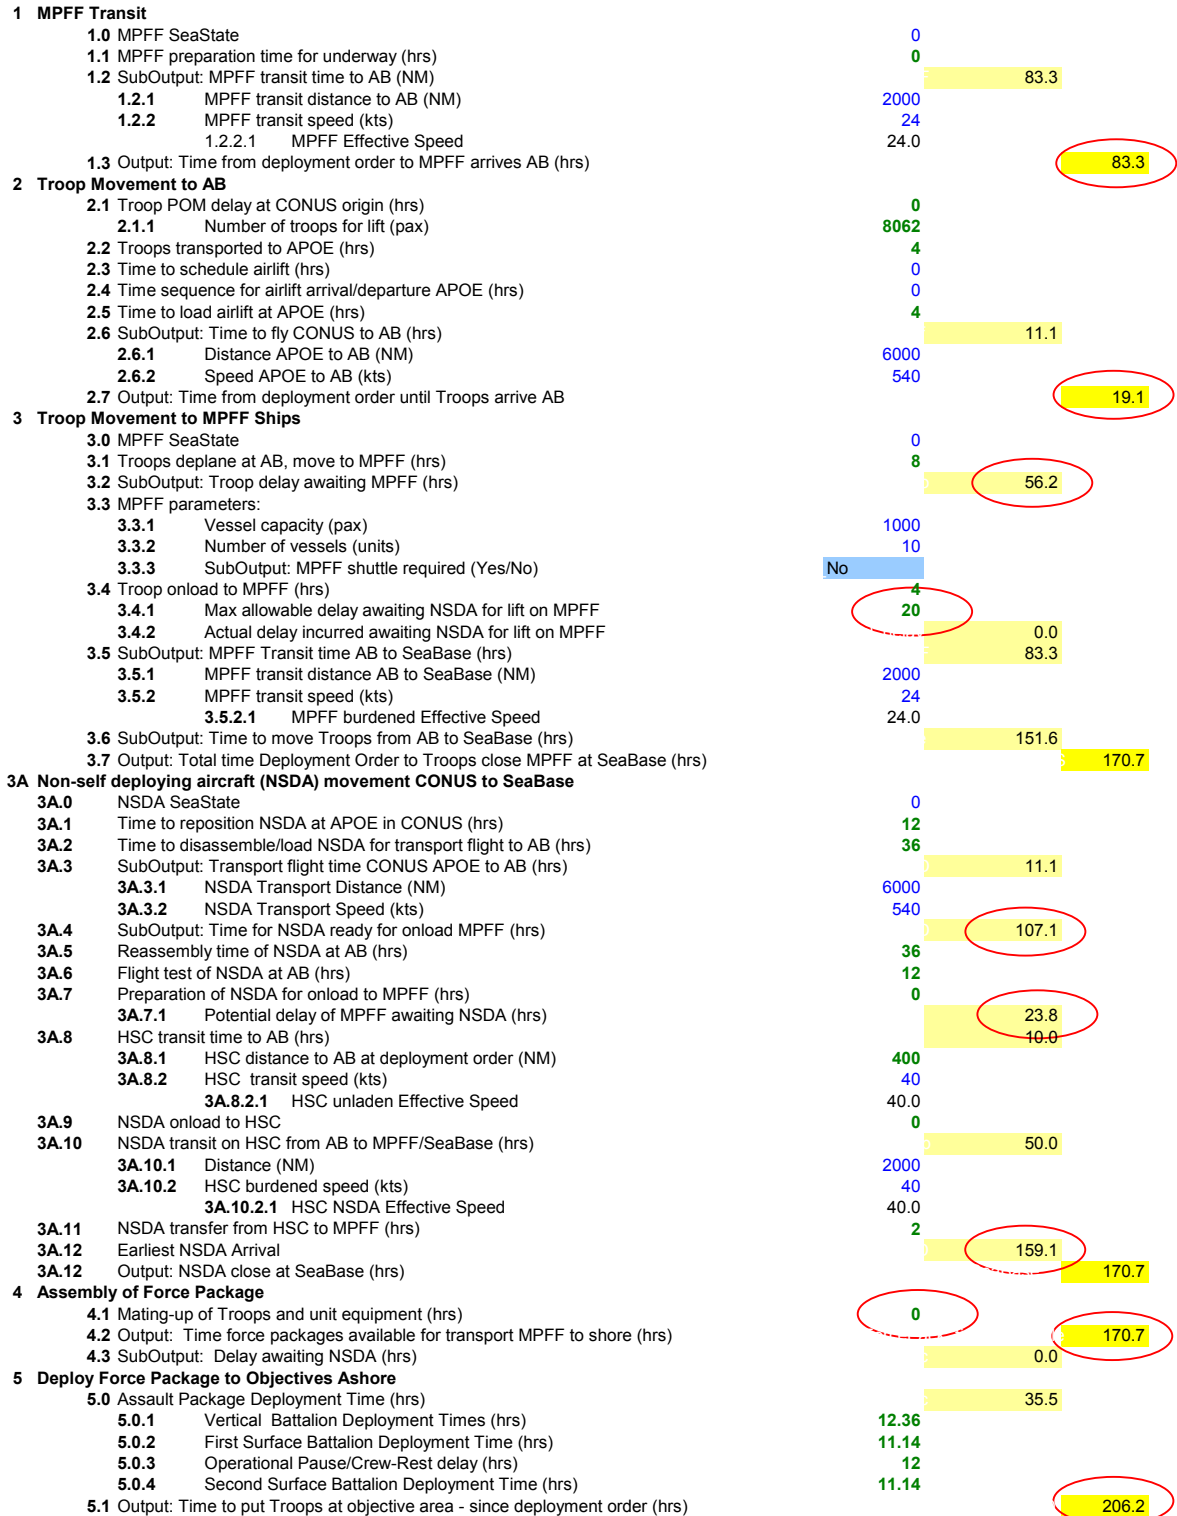

Figure 10. JELO Excel Model, MPF(F) Calls at Advance Base En route to Sea Base

Example 3.1

In this example, troops and NSDA are transported on RSLs to the advance base and the MPF(F) sails from its preposition site to the advance base and serves as the connector. The MPF(F) ships would then sail for the sea base as soon as the troops, NSDA, and cargo could be loaded at the advance base (see Figure 11). Note that the NSDA may be transported in folded, but not partially disassembled, condition.

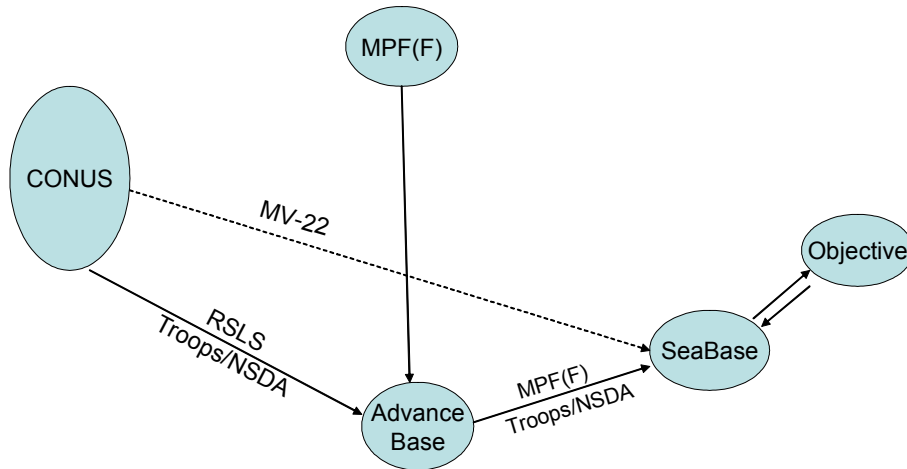

Figure 11. RSLs and MPF(F) Rendezvous at Advance Base

The JELO Flow model for this example is shown in Figure 12. MPF(F) transit is a distance/speed event taking 83.3 hours to transit to the advance base. MPF(F) speed is input as 24 kts here. Troops and NSDA arrive at the advance base at 158.0 hours. They debark, move to and load onto the MPF(F) in 12 hours, and then sail to arrive at the sea base at 253.3 hours. Note that there was no delay awaiting the MPF(F) due to the RSLs' six-day transit to the AB. Because the troops have been aboard the MPF(F) since the advance base, there is no mate-up time with equipment. Finally, deployment to the ashore objective proceeds as before and results in a force closure to objective time of 288.8 hours (12.0 days).

Figure 12. JELO Excel Model, RSLs and MPF(F) Rendezvous at Advance Base

9.4 Summary

The few examples demonstrated here are summarized in the table below where AB denotes the advance base and SB denotes the sea base. Time to close to objective varies from 8 to 18 days, depending on the closure option selected and other assumptions. The two smallest times to close to objective assume Air Mobility Command (AMC) aircraft to transport NSDA are immediately available and in sufficient number, and this is the major, and possibly unrealistic, reason their closure times are the smallest. Example 1 and its derivatives employ a HSC operating between the advance base and the sea base and involve troop transfer at sea. Examples 2 and 3.1 involve RSLs operating from CONUS—one with at-sea troop transfer and the other without. At-sea transfer of troops to the MPF(F) is avoided entirely if the MPF(F) calls at the advance base to embark troops prior to sailing to the sea base, as in Examples 3 and 3.1.

The columns of the table contain only the major features. There was no variation of the large number of parameters of sea-based logistics operations; e.g., geographical distances, sea state, and platform characteristics. Clearly, a plan to evaluate all combinations is not sensible. Rather, the model should be employed to investigate

particular conditions and tradeoffs of interest. The goal in this project was not to conduct sea basing platform and capabilities tradeoffs, but to build a tool for doing such analyses. The examples illustrated the use of the JELO model, but did not in any sense demonstrate a preferred solution.

	MPF(F) Prepo Site		Airlift - CONUS to AB			RSLs from CONUS		HSC	Closure to Objective Time
	To SB	To AB	No Delay	Delay	Multi-Wave	To SB	To AB	AB to SB	
1	X		X					X	8.2 days
1.1	X			X				X	11.6
1.2	X			X	X			X	16.5
1.3	X			X	X			X	18.6*
2	X					X			10.9
3		X	X						8.6
3.1		X					X		12.0

* additional NSDA

10. Sustainment

Once the sea-based maneuver elements have been deployed to their objectives ashore, attention shifts to sustainment. The maneuver elements require daily replenishment of their provisions, water, fuel, and ammo. The MPF(F) ships, whose stocks of combat stores provide the commodities for the daily resupply of the ground forces, will also require replenishment as their stocks are drawn down to the reserve levels. Finally, the other ships of the sea base—the CSG ships and the ESG ships—require replenishment periodically.

10.1 Resupply of the Maneuver Forces Ashore

Once ashore, the maneuver forces consume MREs and water daily, along with fuel to power their vehicles, generators, and weapon systems, and the ammo used in combat. Running out of any of these commodities is a combat stopper. Daily resupply from the MPF(F) ships is intended to replace the commodities used. If the ground forces deploy with two days of supply and the reserve level is one day of supply, the order quantity is one day of supply and the safety level is one day of supply. Deploying with two days of supply is suggested in the literature, but deploying with three days of supply and daily replenishment of one day of supply results in a safety level of two days of supply. The two days of supply safety level is not modeled, but easily could be.

Daily provisions requirements are easily estimated as three MREs per Marine per day. An MRE weighs 1.86 pounds, three of them weigh 5.58 pounds and this then is the planning factor for provisions in pounds per Marine per day (PMD) [4]. Water requirements are also computed PMD with a planning factor of 4-6 gallons per day. The model uses six gallons PMD and a gallon of water weighs 8.3 pounds. The planning factor for water is thus approximately 50 PMD. Water could be provided in bulk in 250-gallon bladders, or in bottled form on pallets. Palletized bottles are modeled so the daily requirement is quoted in pounds rather than gallons. Use of water bladders requires a different load-packaging algorithm.

While the daily food and water requirements of the SBME are easily estimated, the daily fuel requirement is, along with the daily ammo requirement, much more difficult to estimate. Estimates or planning factors in the literature vary by almost an order of magnitude. Some of the estimates are based on the older Marine Corps Bulletin 3501 table of organization and table of equipment for a MEB. The HIMARS and EFSS weapon systems are new to the Marine Corps and ammo-planning factors for them are not available. The 2015 MPF(F) and its SBME are new and fuel and ammo planning factors have not been published. The 2015 MPF(F) MEB is different in numbers, kinds of units, and table of equipment from the Marine Corps Bulletin 3501 MEB. The published logistics planning factors for the consumption of fuel and ammo are based on the 3501 MEB or even earlier versions. The 2015 MPF(F) MEB SBME is smaller and lighter than the 3501 Ground Combat Element (GCE). Whereas the former has 500 vehicles of all types, the latter had 1,711 vehicles. Clearly, the fuel requirements of the SBME will be less than the published logistics planning factors for the 3501 GCE. Likewise, the SBME has only two artillery batteries rather than an artillery battalion and will have smaller ammo requirements than the 3501 GCE.

The methodology adopted for estimating SBME daily fuel and ammo requirements is to take the existing planning factors and the existing table of organization personnel numbers for each type of unit (infantry battalion, artillery battery, LAV company, etc.) and compute the commodity use planning factor in terms of pounds or gallons per Marine per day. These factors are then applied to the SBME table of organization for each of the three reinforced infantry battalions and their small number of direct support personnel. For example, in [12] an infantry regiment of 2,993 troops is estimated to use 1,790 gallons of fuel per day (gpd). This works out to 0.6 gallons per Marine per day (GMD). In [14] a battalion of 1,072 troops was assumed to use 596 gallons per day. This works out to 0.56 GMD. A planning factor of 0.6 GMD was selected and applied to the 934 troops of an SBME infantry battalion yielding an estimate of 560 gallons per day. GMD fuel-use planning factors for other types of units range up to 12.59 GMD for tank companies and 16 GMD for artillery batteries.

The only source of ratios between assault and sustained rates is in [4], and then only for fuel. In [4], the ratios range from 1.5 for infantry to 6.15 for amphibious assault vehicle units. These ratios were used to estimate assault rate fuel use planning factors by type of unit. Summed over the numbers and types of units in the SBME, the estimates of assault rate and sustained rate daily fuel requirements of the SBME ashore are 26,500 gallons during the assault phase of the operation and 11,300 gallons as the sustained operations rate. Twenty percent of these totals are ascribed to the Vertical battalion and 40% to each of the Surface battalions. This methodology produces smaller daily requirements for fuel and ammo than most of the numbers in the literature, but they are perhaps consistent with the changes being made to sea base smaller, lighter maneuver forces. Currently, N42 [5] estimates the MEB will use 1,560 bbl or 65,500 gallons of fuel daily. [4] provides a planning factor for the fuel used daily by a Marine division as 113,000 gallons (assault rate). The SBME daily fuel requirement (assault rate) estimate here is 26,500 gallons. The SBME certainly has smaller fuel requirements than either a Marine division or a full MEB and thus the estimate used here may not be unreasonable.

The same methodology was used to estimate daily ammo resupply requirements. No source of assault/sustain ratios was found, so only sustained rates could be estimated. The PMD planning factors ranged from 2.51 PMD for infantry to 48.35 PMD for artillery. Applied to the kinds of units, the estimates of daily ammo resupply requirements were 7,981 pounds in the Vertical battalion and 14,747 pounds in each of the Surface battalions for a daily total ammo resupply requirement of 37,475 pounds, or nearly 19 tons.

It is assumed that daily replenishment will be delivered vertically and that surface delivery will be used only if the vertical replenishment capability cannot meet all requirements. There will be at least two destinations for the resupply delivery trips: the location of the Vertical battalion and the location of the two Surface battalions. We cannot know the actual geometries, but we do know the desire to keep the sea base well out of harm's way, so the resupply operations are modeled as 110 nm distances from the sea base to either destination. This assumption also allows the daily resupply requirements of the different battalions to be merged into a single requirement that is conservative in the sense that the actual requirement, as far as distance is concerned, could be less demanding.

Doing the arithmetic of 5.58 lbs of MREs PMD and six gallons of water PMD, plus, at assault rates, 26,500 gallons of fuel daily and 37,475 lbs of ammo daily, the total daily resupply requires the movement of nearly 300,000 pounds of dry cargo and 55 500-gallon fuel bladders. The movement model says this will take 5.9 hours utilizing 10 CH-53Xs and 10 MV-22s. If vertical daily resupply is feasible at assault rates, it will also be feasible at sustained rates.

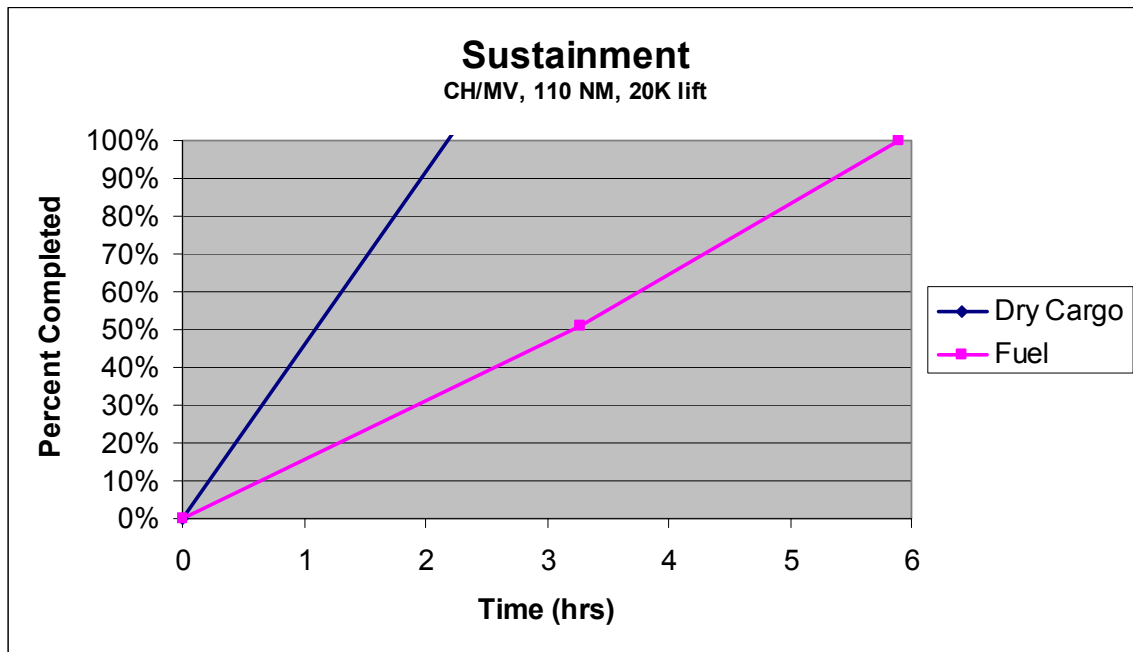

Sustainment at 110 NM / 24 MV22 / 10 CH53 / 2 loading spots

Loads	Start Total	Start Time	End Time	End Total	Spot #'s	Connector	# of connectors	Crew Day Used
Dry Cargo (20k sling)	15	0	3.27	0	1	CH	10	25.3
Fuel Bladder (500g)	55	0	3.27	27	2	MV	8	26.16
Fuel Bladder (500g)	27	3.27	5.9	0	1,2	MV	10	26.3

Time	Dry Cargo	Fuel
0	0	0
3.27	15	28
5.9	15	55

	27		10	1	2.63	0	26.3

10.2 Resupply of the MPF(F) Ships

In the previous section, the daily resupply requirements of the forces ashore were estimated. The food, water, fuel, and ammo are supplied from the stores of the MPF(F) ships. After some time, the levels of these commodities in the MPF(F) ships will fall to their reserve levels (50% is assumed for the reserve levels) and the MPF(F) ships will themselves require replenishment. [3] uses a requirement for the MPF(F) squadron to have 20 days of supply of all commodities for the MEB. (It is unclear whether the MPF(F) squadron is to contain 20 DOS for the whole MEB or just the Seabased Echelon; the whole MEB is not presently seen as embarking the ships of the MPF(F) squadron.) This implies that the reserve levels will be reached on the 10th day of operations. By the 10th day, the total amount of combat stores supplied from MPF(F) ships would be 135 tons of MREs, 1,176 tons of water, 265,000 gallons of fuel, and 187 tons of ammo. MPF(F) replenishment requirements, however, depend on the cargo capacities of the MPF(F) ships for each of the commodities.

The MPF(F) ship implicit in the descriptions here is constrained-size ship with rotary wing (R/W) and tiltrotor (T/R) aircraft only from the MPF(F) Analysis of Alternatives final report [3]. Each of these ships has a cargo fuel capacity of 36,000 barrels. It is assumed that the fuel carried is the standard single fuel, JP-5, that powers both the combat vehicles ashore and the aircraft and LCACs of the MPF(F) ships. If each MPF(F) ship has 36,000 bbl of fuel, the squadron of eight ships has 288,000 bbl. of cargo fuel and the 50% reserve level will be reached when total consumption reaches 144,000 bbl. MPF(F) cargo fuel supports operations of the SBME ashore, MV-22 and CH-53 aircraft operations by aircraft of the MPF(F) squadron, and LCAC operations. Because of the deployment of the SBME, first day fuel consumption is larger than that of subsequent days.

On the first day of operations, MPF(F) aircraft and LCACs are heavily utilized in the deployment of the SBME maneuver forces. The movement model results in Section 8.1 predicted 342 MV-22 flight hours and 147 CH-53 flight hours. A nominal fuel burn rate for the MV-22 is 500 gallons per hour. Likewise, the CH-53 might be expected to burn 600 gallons per hour. These numbers imply a total aircraft fuel consumption for deployment of 6,171 bbl. Likewise, the movement model results in Section 8.2 indicate a total of 127 LCAC operating hours. At 1,000 gallons per hour [14], and for deploying both Surface battalions, the total LCAC fuel use was 6,048 bbl. In Section 9.1, the SBME assault rate fuel use was 26,500 gallons or 631 bbl. Thus, the estimate of total fuel use on the first day is 12,219 bbl. For subsequent days, the MV-22 and CH-53 fuel uses are associated with resupplying the forces ashore and with supporting other operations. Just half of the aircraft were devoted to resupply operations in the model of Section 9.1 and they flew 59.6 MV-22 hours and 25.3 CH-53 hours for a total fuel use of 45,000 gallons or 1,071 bbl. We might assume the other half of the aircraft had a similar flight hour program, though for other purposes, and therefore the total aircraft fuel use on days after deployment is 2142 bbl. After their heavy use in deploying the two Surface battalions, it is assumed that 20 LCAC trips are made daily for a total fuel

consumption of 1,300 bbl. On the other hand, if the MPF(F) ships withdraw to 75-100 miles offshore, it could be argued that there is no LCAC use at all.

To summarize, total first day fuel use is estimated as 12,219 bbl. and following day fuel use totals 4,073 bbl. The reserve fuel level in the MPF(F) squadron would then be reached on the 33rd day of the operations, not the 10th day. The large amount of cargo fuel in this MPF(F) ship design provides for far more than 20 days of supply (more like a 65-day supply). Fuel replenishment to the MPF(F) ships could be provided by commercial tankers operating skin-to-skin in sea states up to 4, as is commercial practice with very large crude carrier operations off the West Coast of the United States.

The constrained-size, rotary wing- and tiltrotor-only design description in [3] does not indicate the amount of dry stores and ammo each ship would carry. Therefore, the 20 days of supply description is used and, along with a 50% reserve level, implies that resupply is needed by day 10 of the operation. With palletized MREs, bottled water, and ammo loaded into containers, and if containers can be transferred from commercial container ships at sea in open ocean—either through skin-to-skin transfer or stabilized crane—replenishment could be accomplished with commercial ships. If the time line is such that it takes at least ten days to close to the sea base and a day for force assembly, the 10th day of operations is 21 days after the deployment order. This may be sufficient time to allow the charter of container ships, their loading, and their transit to the sea base. The impact of this, if correct, is that there may not be a requirement for ships dedicated to replenishing the MPF(F). Alternatively, resupply of the MPF(F) could be provided by a ship of the squadron being offloaded to the other ships in the squadron and then serving as a shuttle ship.

10.3 Resupply of the CSG and ESG Ships of the Sea Base

Exclusive of the submarine, the Navy Fact File describes a carrier strike group as a CVN-68 class carrier, a GC-52 class cruiser, two DDG-51 class destroyers, and a T-AOE-6 class station ship. An expeditionary strike group, exclusive of the supporting submarine, is described as an LHD or LHA, an LPD, an LSD, a CG-52 class cruiser, a DDG-51 class destroyer, and a FFG-7 class frigate [15]. Notably, the ESG has no station ship.

Using OPNAV N42 logistics planning factors [5] the following data are compiled.

		Capacity (bbl.)	Daily Usage (bbl.)	DOS	Days to 50%
CSG	F-76	99,392	2,951	33.7	16.8
	F-44	118,283	5,034	23.5	11.8
	Ammo (tons)	3,971	100*	39.7	19.9
ESG	F-76	115,712	3,348	34.6	17.3
	F-44	19,306	1,062	18.2	9.1
	Ammo (tons)	549	36*	15.3	7.6

The asterisked numbers require amplification. The 100 tons of ordnance use by the CSG is the lower number in the N42 file. The lower number may still be too high. In Vietnam the planning factor was 188 tons of strike ordnance per day, in Desert Storm the number was a third of this daily tonnage, and the substitution of precision for mass continues through OEF and OIF. The 1,062 bbl. of F-44 is rather larger than the 348 bbl. in the N42 file. The 1,062 bbl. per day represents four flight hours by each of the ESG's 12 MV-22s, four flight hours by each of the ESG's four CH-53s, and a 2.75-hour sortie by each of the ESG's four LCACs. Finally, the ESG's 36 tons of ordnance per day is the lower of the two numbers in the N42 file.

There is clearly a lot of anxiety over the right planning factors. The analyst using JELO can edit any of this as better information becomes available.

The least sustainability arises from the ESG's limited F-44 capacity, limited ammo capacity, and the fact that the ESG has no station ship. The CSG's station ship could help this situation if it serviced the ESG's F-44 needs and was loaded with both Navy strike ordnance and USMC strike and ground combat ordnance (this is not presently the case).

A pencil and paper analysis indicates that two T-AOs and one T-AKE shuttling to and from an advance base 2,000 nm distant from the sea base can more than satisfy the fuel and ordnance requirements of one CSG and one ESG. Multiples of the numbers of CSGs and ESGs do not scale the requirements linearly, however. An integer program implemented in the General Algebraic Modeling System (GAMS) has been used offline to evaluate the numbers and types of shuttles required to maintain commodity levels for various combinations of CSGs and ESGs, assuming every CSG has a T-AOE station ship [16]. The table is presented below.

#CSGs	#ESGs	Req'd/no F-44 reserve violation		Req'd/limited F-44 violation	
		T-AKE	T-AO	T-AKE	T-AO
1	1	1	2	1	1
1	2	1	2	1	1
2	2	1	3	1	2
3	3	1	3	1	2
4	4	1	4	1	3
5	4	1	5	1	4

11. Conclusion

Some of the major logistics issues associated with sea basing expeditionary maneuver warfare have been described in this report. A spreadsheet model of the end-to-end process of force closure to the sea base and deployment to objectives ashore has been developed. In all of this there are significant uncertainties about platform specifications and capabilities and about logistics planning factors for combat stores usage. While every effort was made to find or develop and use sensible data, almost all model parameters may be user specified. This report contains a number of examples that

demonstrate the use of the movement model, the deployment model, and several of the possibilities for closing the force to the sea base. The goal of the project was to create a tool to evaluate platform and capability tradeoffs and support programmatic decision-making.

Some observations drawn not so much from exercising the model as simply from studying the problem are as follows. A requirement to keep the sea base 100 nm at sea because of the sea-skimming missile threat imposes serious difficulties. Among other things, it means that the LCACs and EFVs are disenfranchised unless there is some new high-speed assault connector that can carry them closer to shore. This is a problem at the intersection of Sea Shield and Sea Basing.

The issue of moving non-self-deploying aircraft to the sea base is important. Deployment and sustainment don't take place without them and they may be the last equipment to arrive at the sea base. More generally, where all the connectors—air and surface—are when the deployment order is given is an important issue.

It may turn out that for many scenarios, the MPF(F) preposition site is also the nearest advance base. In this case, holding the MPF(F) to wait for the arrival of the troops from CONUS may not delay things very much and avoids the need for a HSC and HSC to MPF(F) transfer operation. This may be attractive, but the problem of getting the NSDA to the sea base remains.

Finally, while there is much interest in high-speed sealift and high-speed connectors, the speed of the MPF(F) ships would seem to be an important variable in the problem. MPF(F) speed limits the early arrival of the MPF(F) to the sea base and is even more critical if the MPF(F) waits to embark troops at the advance base/preposition site before departing for the sea base.

The Navy and Marine Corps are striving to define the MPF(F) and determine what its capabilities and capacities need to be. Additionally, there are potentially other platforms to build in order to make Sea Basing a reality—high-speed connectors, assault connectors, and rapid strategic lift ships. JELO can be of use in evaluating the alternatives.
