## **ABSTRACT**

The threat posed by malicious software and networked adversaries to computers has resulted in the development of mechanisms to provide assurance that security sensitive information is not being compromised. One such mechanism is called a Trusted Path. A Trusted Path provides a protected communications channel that permits the computer to authenticate itself to the user and for the user to authenticate to the system.

This thesis provides a demonstration implementation of a Trusted Path for Security Enhanced Linux (SELinux) and is used to examine trusted paths, their design and implementation. Additionally, the effectiveness of a Trusted Path for SELinux is analyzed.

This research is meant to provide a framework that could be used in combination with other efforts to enhance the security of SELinux.

# I. INTRODUCTION

## A. OVERVIEW

The widespread incorporation of computing systems into the everyday lives of average people has led to the realization that computers need to be ‘secure’. There are numerous news articles which describe computer security concerns as well as the ‘hack’ of the week. Why computers need to be ‘secure’ can be readily described in terms of the need to protect information. Governments, businesses and individuals rely on information stored in computers to be correct, safe from eavesdropping and to be readily accessible. In computer security terms, the user needs assurance that his information stores support confidentiality, integrity and availability.

The need for computer security is not new but the requirement is increasing as more information is stored electronically and the number of interconnections between computer systems increases. As a small part of the general research in computer security subjects, this project will explore the implementation of a trusted path in Security Enhanced Linux (SELinux). This version of Linux is part of a National Security Agency (NSA) research project pursuing architectures for more secure operating systems. The addition of a trusted path to SELinux would increase the user’s protection from password sniffing software and is a common security feature in medium and high assurance operating systems.

## B. HISTORICAL BACKGROUND

Following quickly the development of general purpose computing machines, concerns about computer security arose. Initially the concerns were focused on non-malicious activities that could affect other computer users or that could cause inadvertant corruption of the operating system, but it soon became apparent that malicious behavior could be a threat. In 1970, a Rand report by Ware [1] described some of the potential computer security threats to the Department of Defense. The Ware report also made some general recommendations as to approaches to address the issues but it fell short of providing a concrete general purpose solution to the problems.

A general solution to the computer security problem was proposed in a paper by Anderson in 1972 [2]. Anderson's proposal was to create a reference monitor that would oversee all security related activities on the computer. Specifically, the reference monitor would ensure that all data accesses were correct in terms of permissions and actions. The reference monitor is generally accepted as an idealized mechanism to provide security in a 'high-assurance' computer system. Another related concept is the Trusted Computing Base (TCB). In the National Information Assurance Glossary [3], the TCB is defined as the

[t]otality of protection mechanisms within a computer system, including hardware, firmware, and software, the combination responsible for enforcing a security policy.

The TCB consists of more than an implementation of a reference validation mechanism and includes such things as identification and authentication, the security administrator interface, audit retrieval and analysis functions [4].

A potential security problem with computer systems is that it is possible to write a computer program that can impersonate the login process or other security sensitive operation. This could allow the capture of a user's password and ID. This area of concern was identified as early as 1975 by Saltzer and Schroeder [5]. The idea of ensuring that a user was talking to the 'Trusted Computing Base' was required for some levels of computer assurance in the 'Orange' book [6].

DoD 5200.28-STD: The TCB ("Trusted Computing Base") shall support a trusted communication path between itself and user for initial login and authentication. Communications via this path shall be initiated exclusively by a user.

This trusted communication path is generally termed a *trusted path* and is needed to give the user assurance that he is indeed communicating with the trusted computing base and not some software spoofing the TCB. Conversely, it also provides assurance that the operating system is connected to the user. The *trusted path* is important when the user identifies himself to the computer through the use of some sort of authentication process to avoid the malicious capture of the user's authentication information.

## **C. PURPOSE OF STUDY**

### **1. Scope and Assumptions**

This thesis will assess the requirements for a Trusted Path in Security Enhanced Linux. The publicly available information about the various Trusted Path implementations will be reviewed in an attempt to identify significant design considerations. After reviewing previous work in this area, a design for a Security Enhanced Linux implementation of a Trusted Path will be proposed and implemented.

### **2. Research Objectives**

The Information Assurance Research Office of the National Security Agency (NSA) has worked with various research organizations to develop Security Enhanced Linux [13]. One purpose of NSA's research is to provide a demonstration project of how mandatory access controls (MAC) can be used to confine processes to prevent security issues. The project is also working on developing a security implementation architecture that is flexible enough to allow for the implementation of various security policies [17].

The research presented in this paper is meant to provide a design document for Trusted Path implementation using the Security Enhanced Linux as a demonstration project.

## **II. OVERVIEW OF SECURITY ENHANCED LINUX**

### **A. BACKGROUND**

Information assurance is a very active concern of the U.S. government, especially in the agencies and departments that deal with highly classified information. It seems reasonable that Top Secret information stored on computers should be protected from unauthorized disclosure, e.g. protected from computer hacking. The National Security Agency (NSA) is concerned with systems that are capable of protecting the agency's sensitive information. As a result, the NSA conducts research in improving computer security, and operating system security is an area of particular interest.

One of the current computer security debates is whether "open source" software is more secure than proprietary software. This discussion pertains to the relative security of each of the software models. The Linux operating system is the most commonly identified open source software in these discussions and is identified as open source because the source code is freely available. Most of the development of Linux is performed by various volunteers throughout the world. Proponents of open source believe that the availability of the source code for review by all users improves security. These users provide a potentially large number of reviewers to identify and correct some of the potential vulnerabilities. Others believe that the availability of the source code allows users to modify it to meet their particular security needs. Another potential advantage for open source software is the ability of the multitude of developers to react quickly to discovered vulnerabilities by providing software patches.

At the other end of the spectrum is proprietary or closed source code software, such as the Microsoft operating system. Proponents of these types of products believe that open source products provide the potential hacker with an advantage in finding potentially exploitable vulnerabilities. They also cite the responsiveness of the commercial software industry as a key factor in providing the needed security.

An argument can also be made that by controlling the software from design through implementation to final delivery gives the commercial software company the ability to ensure security of the product. While this control of the entire product could help ensure the security of the system, in practice, it does not appear to function that way. Many commercial products have had additional software functionality, commonly referred to as ‘Easter Eggs’, embedded in the product by the implementation team. Some Easter eggs have included significant amounts of code such as the flight simulator found in an older version of Excel. Additional information about this and other ‘Easter Eggs’ is available at the Easter Egg Archive [28]. If the implementers can include an unauthorized flight simulator what prevents the addition of more malicious functionality by a member of the team? Witten, et al., [21] provides an excellent discussion of some aspects of the subject.

Ultimately, open vs. closed source is not particularly relevant to medium or high assurance software as defined by the U.S. Government. Open and closed are really economic models that describe how groups generate profit from the software. Assurance or computer security could potentially be provided under either model. What provides the needed assurance is the rigor of the development methodology. Without a formal and methodical approach to the design, implementation, testing, configuration management, etc., software will continue to have large numbers of bugs, including those that are security related, regardless of the economic model of the software. Generically, computer systems that have undergone a formal security design process can be termed trusted systems because of the assurance provided by the process.

Trusted computer systems have many characteristics that make them distinct from commonly used systems [2]. The lack of mandatory access controls (MAC) was identified as functionality absent from most ‘mainstream’ operating systems. As a result, NSA developed a MAC architecture that could be used for many current operating systems and flexible enough to allow a wide range of security policies to be applied. This architecture is known as Flask and Security Enhanced Linux (SELinux) is a research prototype of the Flask architecture [12].

Flask separates policy from enforcement as a means of increasing the flexibility of the system. NSA had a generic security policy built by NAI labs to support the SELinux demonstration project. SELinux provides some support for multilevel security but the implementation is incomplete at this time and is not used regularly within the SELinux user group. The selection of Linux as a demonstration platform for Flask was driven by the open source nature of the ongoing development and the desire to improve the security of a widely used platform [12].

## **B. SELINUX SECURITY OVERVIEW**

The remainder of this section will address the specifics of the Flask demonstration implementation and its generic security policy. The following is based on the version of SELinux for the Linux 2.6 kernel. This kernel adds support for extended security attributes and made significant changes to the previous SELinux implementations.

SELinux can be viewed as having two primary components: a security policy and the enforcement mechanism. Policy is contained in the security server and enforcement is performed by object managers.

The security server is responsible for the security policy and for making determinations about security access. This server is located in the kernel as a subsystem and provides application program interfaces (API) that the object managers can query for security determinations. For example, if a user attempts to access a file, the file system object manager will submit the user credentials and the file attributes to the security server to determine if the user has the authority to access the file in the manner requested. The server is also responsible for security of the security policy.

The various object managers enforce the policy decisions of the security server. Object managers include kernel subsystems such as process management, file system, and socket IPC. When a process attempts to access an object for the first time, the object manager contacts the security server with the security contexts. The security server performs a look up to determine if a specific access is allowed and returns a decision to the calling object manager. The object managers may cache the decision in an access vector cache (AVC) in order to speed up recurring accesses. There is a mechanism to allow revocation of access permissions if the policy changes while an object is open.

This revocation mechanism is described as the most complex aspect of the Flask architecture in [10] and requires additional communication between the object managers and the security server to allow updating of policy settings even if an object is open.

## C. SELINUX SECURITY CONCEPTS

### 1. Type

Each object, such as directories, files, and sockets, is assigned a type. An access matrix is created that contains allowable accesses between types. An access must be explicitly defined as allowable per the SELinux implementation of principle of least privilege. There are more than 140 different types in the default SELinux installation and they are grouped into seven categories:

- Device
- Devpts –pseudo terminal devices
- File
- Network
- Network File System
- Procs – process context file system
- Security

### 2. Domain

Each process runs in a domain. The domain controls what the process can access. It is very much like the idea of types for objects and is stored in the same data structure as the types. There are in excess of 160 domains in a default install of SELinux including admin, user, auth-net, fcron, kernel, startx, and more than 150 various program domains.

### 3. Identity

Each user has a SELinux identity in addition to a standard Linux user ID. This can be confusing because the identity and ID are typically the same name. Normal commands that can change a Linux ID, e.g. su, do not change the SELinux identity.

Example:

```
Root performs an id command
root@localhost selinux]# id
uid=0(root) gid=0(root) groups=0(root), 1(bin), 2(daemon),
3(sys), 4(adm), 6(disk), 10(wheel)
context=root:sysadm_r:sysadm_t
```

#### Root su's to ahilchie

```
[root@localhost selinux]# su - ahilchie
```

#### Root performs an id command as ahilchie

```
[ahilchie@localhost ahilchie]$ id
uid=500 (ahilchie)    gid=500 (ahilchie)    groups=500 (ahilchie)
context=root:sysadm_r:sysadm_t
```

In the example above the *uid*, *gid*, and *groups* are the Linux identity while the *context* is SELinux identity information.

#### 4. Role

A role is a collection of domains that some grouping of users can enter. Currently, the domains that a particular user can enter are identified in various configuration files.

#### 5. Security Context

A security context consists of an identity, a role and a domain or type.

Example contexts:

	<u>identity:role:domain or type</u>
Init process	system_u:system_r:kernel_t
Root	root:sysadm_r:sysadm_t
User	ahilchie: user_r:user_t

#### 6. Transition

Transition decisions are made to determine the correct security context for a particular operation. As an example, if a user (ahilchie) creates a new file in his home directory, it will have a security context of ahilchie:object\_r:user\_home\_t but the same file in the /tmp directory would be ahilchie:object\_r:user\_tmp\_t.

### D. SELINUX SECURITY ASSESSMENT

SELinux is not a high assurance system. It is Linux with additional security policies. There has been no attempt to correct any deficiencies in the underlying operating system. As noted on the NSA SELinux web page:

This work is not intended as a complete security solution for Linux. Security-enhanced Linux is not an attempt to correct any flaws that may currently exist in Linux. Instead, it is simply an example of how mandatory access controls that can confine the actions of any process, including a superuser process, can be added into Linux. The focus of this work has not been on system assurance or other security features such as security auditing, although these elements are also important for a secure system. [17]

Security system subversion remains a very real possibility. It would be possible to create a program and add it to a Linux distribution. Properly coded, the added program could provide any desirable level of access to the system. As an example of the potential, consider Karger and Schell's suggestion of a compiler trapdoor [20] which was elaborated by Ken Thompson in his discussion of UNIX system security [15]. For a discussion of the threat of subversion see Anderson, et al [19]. The inclusion of programs in the Linux source tree is not tightly controlled nor are the programs rigorously examined (in a formal methods manner) prior to being added.

A more simplistic attack vector would be to use some current exploit against the Linux kernel. These exploits are uncovered regularly and, depending on the properties of the exploit, might allow a malicious user to subvert the SELinux MAC policy and take control of the system.

Security Enhanced Linux is a fairly complex overlay to the Linux operating system and contains in excess of 350 configuration files. The Linux system is also a complex system. Complexity is a serious challenge to security for a number of reasons [2]. This complexity presents very real challenges to administration of the system.

### III. COMMON CRITERIA TRUSTED PATH REQUIREMENTS

Traditionally, trusted computing systems have been predominately used by governmental organizations<sup>1</sup>. This chapter will look at the U.S. Government requirements for a *trusted path* in these types of systems. This review of governmental standards will provide a framework for the demonstration implementation of the Security Enhanced Linux trusted path. There has been considerable effort made by many people to identify and codify various aspects of assurance that can be leveraged in this project.

The U.S. Government and many other nations have adopted the Common Criteria as the security standard for computing systems. The Common Criteria identifies a Security Functional requirement class, 'FTP: Trusted Path/channels' [7]. The Trusted Path class identifies several requirements for a trusted path including:

Trusted path requires that a trusted path between the TSF<sup>2</sup> and a user be provided for a set of events defined by a PP/ST author. The user and/or the TSF may have the ability to initiate the trusted path.

The TSF shall provide a communication path between itself and local users that is logically distinct from other communication paths and provides assured identification of its end points and protection of the communicated data from modification or disclosure.

The TSF shall require the use of the trusted path for initial user authentication.

In other words, the trusted path must be an unforgeable communication mechanism between the user and the TCB. Once the user initiates the trusted path, he can be certain that the TCB has taken control and as long as the user remains in the trusted path, then, there is confidence that any software trying to spoof the TCB is thwarted.

---

<sup>1</sup> Evaluated systems have been predominately used by governments; it could be effectively argued that commercial enterprises should have a significant interest in these systems as well. For the government, the compromise of sensitive information could have dire consequences. The same argument is applicable for businesses. The compromise of some types of sensitive business information could even result in the complete failure of the business.

<sup>2</sup> Target of Evaluation Security Functions – Parts of the system that have to be relied upon for enforcing security policies

The Common Criteria allows for the TSF to initiate a trusted path. This capability on the part of the TSF would either degrade the level of security and/or significantly increase the complexity of the TCB. Typically the trusted path is entered into by the system reacting to some user action. The TCB reacts to the user input and provides assurance that the communications between the user and the TCB are protected. If the system is allowed to initiate a trusted path, the user would be unable to determine if the communications path is to the TCB or to a spoofing program. This implies that the TCB would have the responsibility to prevent any system output that appears to be a trusted path. While this may be possible, it would increase the complexity of the TCB's responsibilities with regard to system output and therefore, reduce the system security.

The National Information Assurance Partnership (NIAP) is an affiliation between the NSA and Common Criteria Vendors. NIAP maintains a Public Interpretations Database [8] of determinations made by the Interpretation Board. These are meant to provide additional details of the security requirements required under the Common Criteria. The NIAP Interpretation I-0191: *Minimum Set Of Actions That Require Trusted Path* identifies the following required functions:

- Authentication.

- Session establishment where identification is provided.

- Requests to change the subject sensitivity label.

- Requests to display the current subject's complete sensitivity label.

- Requests to assume a security administrative role.

This list identifies a set of actions which if implemented by the operating system must use the trusted path mechanism. The common thread in the listed items is that they have some security sensitive function. In the case of authentication, the user is providing some sensitive user identifying information (typically a password) that must be protected from entities outside of the TCB. Performing security sensitive actions on a system also requires that the administrator ensure that he is dealing with the TCB prior to issuing security relevant commands.

The sensitivity label requirements are for multilevel systems. These are computer systems that are used to process information at different levels of sensitivity and where there is a requirement to prevent information 'leakage' between different sensitivity levels. A concrete example of a multilevel secure system would be a single computer where both Top Secret and Secret information is processed. It is important to ensure that no Top Secret information can be accessed by a non-Top Secret process. If some software at the Secret level was able to spoof being a Top Secret process, it is possible that information could be compromised. The trusted path provides the authorized user with the ability to select the appropriate level for a session.

Another aspect of the Common Criteria framework are protection profiles. A protection profile is essentially a high level, abstract statement of system security requirements. An organization, such as a government, could create a protection profile, thus stating its security requirements. In this situation a user might be a specific government agency with specific requirements for security. This agency would then develop a protection profile that identifies all of its security requirements. Vendors would then be able to develop products that meet the protection profile requirements. For this project, there is no protection profile identified so we assume that the desire is to have a medium assurance system and design the trusted path to meet an evaluated assurance level 4 (EAL4) requirements.

## IV. AN ABSTRACT TRUSTED PATH

The previous chapter defines the basic requirements of a trusted path. The primary requirement was that the trusted path must provide an unforgeable communication path between the user and the trusted system. This path is invoked by the user and must be evoked under certain conditions.

Open source documentation of trusted path design is limited in availability, therefore, this section will attempt to explore the design considerations for an abstract trusted path. “Abstract” is used to mean that the trusted path design considerations are removed from the actual details of the operating system and the computer hardware.

### A. ASSUMPTIONS

This abstract trusted path will be confined to analysis of the trusted path as a local problem, i.e., the users will be at the system’s local terminal. This paper will not address the more complex issue of a network trusted path. This project will also focus on a single user system in a single level security environment. In the design, we will attempt to allow the basic structure to be extendable to multi-user multilevel environments but these features are not part of the project.

It is assumed that the security policy requires that each user must authenticate to the system through the trusted path for each and every computer session.

A trusted computing base (TCB) is assumed to exist and is not corruptible. The evaluation assurance level of the TCB must be commensurate with that of the trusted path and vice versa. An implementation of a trusted path might be likened to installing very secure external doors in a house. These external doors might be impregnable but the security of the house is also dependent upon preventing unauthorized access from windows, walls, etc., as well. The addition of a trusted path to Security Enhanced Linux will not correct any potential pre-existing vulnerabilities in this operating system.

## **B. THREATS**

Any security relevant design should be based on a ‘threat model’. This means that potential threats to correct functioning should be identified in order to develop strategies to counter those threats. A human metaphor will be used to develop the potential threats.

Alice (our user) has a secret (her password) that she wants to give Bob (our TCB). Crafty Hacker is the enemy and he wants to steal Alice’s secret or, in some cases, keep Bob from getting it. Alice knows Bob and so her trusted path is achieved by the physical recognition of Bob. How can Crafty accomplish his goals?

He could lurk around the corner and eavesdrop on the conversation.

He could pretend to be Bob (perhaps he is a master makeup artist).

If these two approaches fail, he could then prevent Alice and Bob from meeting in a secure manner (standing between them)?

In the computer security parlance:

### **1. Sniffing**

Essentially this is eavesdropping on the conversation. In our trusted path scenario this would require modifying some of the software used for the trusted path to allow redirection of the data.

### **2. Spoofing**

This is impersonating some portion of the trusted path or TCB to allow capture of the sensitive data. Spoofing the logon process with a fake logon screen that accepts the user logon information, throws an error, and then starts the real logon process would be the classic example. A more sophisticated approach would be a man-in-the-middle attack where the spoofing software pretends to be the user to the TCB and the TCB to the user.

### **3. Denial of Service**

DOS is the preventing of transmission of information. A process could be created with the purpose of preventing valid users or the TCB from accessing the trusted path.

#### **4. Circumvention of the Trusted Path**

There exists one other threat to our trusted path: circumvention of the trusted path. This circumvention is described as system subversion and is defined as ‘... the covert and methodical undermining of internal and external controls over a system lifetime to allow unauthorized or undetected access to system resources and/or information.’ [18] The extent of the subversion threat is discussed in Anderson et al 2004 [19]. The subversion problem could be exemplified by a backdoor being installed in the system in order to avoid having to use the trusted path.

The high level system goals will be presented and then the methodology to prevent the threats will be developed.

#### **C. SYSTEM GOALS**

A user needs assurance that he is communicating with the trusted computing base prior to performing security sensitive operations. Examples of security sensitive operations include authentication, changing passwords and performing some administrative actions. The special case of authenticating to the trusted computer base will always occur at the beginning of a session and precedes other trusted path operations. Security sensitive operations will occur after the user is authenticated and while in the trusted path. Also, we may want to support authentication as a different role during an established session, e.g., su to root in the Unix sense.

How does the user invoke the trusted path? Any input methodology could potentially be made to work. This could be as simple as a keystroke combination or as complex as the use of a smart card inserted into a system card reader. Many current computer systems use either a keystroke combination, the mouse position or a click on the screen. Examples of the keystroke approach are found in the XTS 400 system [23] or the Windows 2000 operating system [24]. Trusted Solaris systems use the position of the mouse [25]. It would even be reasonable to have a separate button on the computer to invoke the trusted path. Generically the method to invoke a trusted path is referred to as a secure attention key (SAK).

How does the user know that the trusted path is in effect? Once again there is a range of potential ways to inform the user that the trusted path is in effect. The only real limit on this is the output capability of modern computers. Approaches could include some special LED on the computer or computer monitor that would only be on if the trusted path was in effect. Trusted Solaris has a special area on the screen that can not be affected by non-TCB processes. A simple approach is to guarantee that pressing the SAK always invokes the trusted path. This appears to be the approach used by the XTS 400 and in the Windows NT family. The TCB must be able to protect the SAK invocation; in other words, once the SAK is initiated, no process should be able to prevent that signal from reaching the TCB. This will prevent some process from intercepting the SAK and presenting a spoofed trusted path.

Once the trusted path is invoked, the input and output from the trusted path must be protected from any and all other un-trusted processes. Conceptually this could be achieved by approaches such as terminating or suspending any running un-trusted process. Another approach would be to create a separate and isolated process for use by the trusted path; the major concern in this approach would be to prevent the other processes from gaining access to the terminal.

#### **D. SUBVERTING THE SYSTEM GOALS**

Sniffing and spoofing threats can be avoided by careful design. Toward that end, there are two design facets that need to be addressed. First, that the SAK must always be controlled by the TCB and second, the TCB must block any input and output from untrusted software while the trusted path is in effect. The combination of these two design facets will prevent both sniffing and spoofing of the trusted path communication.

Preventing denial of service (DOS) is more difficult because the problem is larger than the trusted path. There is no way for the trusted path to prevent the majority of DOS attacks. A type of attack that the trusted path would be unable to prevent is unplugging the computer. In terms of the trusted path, what types of DOS attacks should be prevented? Any set of non-TCB processes should not be able to prevent a user from invoking the trusted path. This may be achievable within the TCB and requires that the

TCB process keyboard interrupts correctly. If the TCB can guarantee that the SAK generates an interrupt, which can be used to start the trusted path, then the problem is adequately solved. This does not solve all potential denial of service issues.

The last threat is the circumvention issue. This project will not attempt to address all manner of system subversion. Only a high assurance system, such as those constructed to meet EAL 6 and EAL 7 criteria, can provide any confidence that the system has not been subverted

#### **E. DESIGN APPROACHES**

A primary design goal is simplicity. Saltzer and Schroeder identified complexity as a major security issue in their seminal work in 1975 [5]. This implementation will attempt to minimize complexity unless doing so will reduce security. Most of the high level design decisions are made based on this goal. These include:

- The trusted path shall be activated by a keystroke combination (SAK).
- Pressing the SAK shall always invoke the trusted path.
- The software implementation of the trusted path should be as small as possible.
- The trusted path mechanism will be as simple as possible. For example, the trusted path will not use a ‘windows style’ graphical display due to the large amount of code that would have to be trusted.
- The other running processes will be isolated from the trusted path to prevent them from being able to communicate with the trusted path, keyboard or the computer monitor.
- The authentication mechanism shall only accept input from the trusted path.

## V. DESIGN REQUIREMENTS FOR THE SECURITY ENHANCED LINUX TRUSTED PATH

The Common Criteria defines three functional requirements for a medium assurance trusted path. The preceding abstract trusted path discussion identified some additional design goals. This chapter will present the specific design requirements that were used in this project to design the SELinux trusted path.

### A. COMMON CRITERIA REQUIREMENTS

The Common Criteria Security functional requirements document [22] provides a template that allows system designers to select from various phrases to build a Common Criteria protection profile. As an example, the following is the first Common Criteria requirement for a trusted path:

FTP\_TRP.1.1 The TSF shall provide a communication path between itself and [selection:remote, local] users that is logically distinct from other communication paths and provides assured identification of its end points and protection of the communicated data from modification or disclosure.

Based on the requirements for this demonstration implementation the ‘local’ phrase is selected to generate the following statement. Similarly the two other Common Criteria trusted path requirements are chosen to create our protection profile statements:

#### 1. FTP\_TRP.1.1

The TSF shall provide a communication path between itself and local users that is logically distinct from other communication paths and provides assured identification of its end points and protection of the communicated data from modification or disclosure.

#### 2. FTP\_TRP.1.2

For FTP 1.2 the selection was: The TSF shall permit local users to initiate communication via the trusted path.

#### 3. FTP\_TRP.1.3

For FTP 1.3 the selection was: The TSF shall require the use of the trusted path for initial user authentication.

#### **4. Function Requirement Discussion**

FTP\_TRP.1.1 really defines a trusted path. The requirement states that the trusted path must provide an unforgeable communications link between the user and the trusted portion of the operating system. The trusted path must also ensure that, once established, any information passed between the user and the TSF must be protected from modification and disclosure.

FTP\_TRP.1.2 requires that a user must be able to invoke the trusted path.

FTP\_TRP.1.3 states that initial user authentication shall be conducted using the trusted path.

#### **B. NON-FUNCTIONAL REQUIREMENTS**

In addition to the functional requirements there are guiding design principles that are important to designing security features. Primarily these principles include simplicity, modularity and appropriate layering of the design.

Simplicity is a very important design consideration which enhances the understandability of the code. Increasing complexity increases the probability that serious design flaws will exist and decreases the chance that these flaws will be discovered during design review. Additionally, increased complexity leads to an increase in the likelihood of implementation mistakes.

Modularity and layering are related to simplicity in terms of design. Designing the modules and layers to group similar or related behavior enhance the understandability of the design. Placing functionality at the appropriate layer provides the same benefit.

#### **C. REFINING THE FUNCTIONAL REQUIREMENTS**

The SELinux trusted path has three functional requirements plus several non-functional requirements. Based on the proposed design, this section defines how this implementation meets the common criteria functional requirements for a trusted path using functional supporting requirements (FSR). These supporting requirements are simply the elements that this design needs to be able to meet the common criteria requirements.

### **1. Functional Sub-Requirements Supporting FTP\_TRP.1.1**

FSR 1 – The TSF provides a trusted path menu to allow the user to select the appropriate action to be performed.

FSR 2 – The TSF suspends all non-trusted path user processes associated with the user upon entering the trusted path.

FSR 3 – The communication path between the keyboard or computer monitor and the TSF shall be under control of the TSF while the trusted path is active.

### **2. Functional Sub-Requirements Supporting FTP\_TRP.1.2**

FSR 4 – The TSF is always notified of the secure attention key (SAK) signal.

### **3. Functional Sub-Requirements Supporting FTP\_TRP.1.3**

FSR 5 – User authentication is controlled via the trusted path.

FSR 6 – Pressing the SAK when there is no authenticated user results in the TSF initiating an authentication sequence.

FSR 7 – Failed authentication results in returning to the initial pre-authentication state.

FSR 8 – Successful authentication results in the display of the trusted path menu.

### **4. Additional Functional Sub-Requirements**

The following two sub-requirements are necessary to provide appropriate functionality to the SELinux trusted path.

FSR 9 – Selecting *run* from the trusted path menu restores any previously suspended user processes or causes a new shell process to be spawned.

FSR 10 – Selecting *exit* from the trusted path menu terminates any user processes and returns the computer to the pre-authentication state.

These 10 functional supporting requirements are sufficient to meet the Common Criteria functional requirements, and support some additional desirable functionality as well.

THIS PAGE INTENTIONALLY LEFT BLANK

## **VI. HIGH LEVEL DESIGN FOR THE SECURITY ENHANCED LINUX TRUSTED PATH**

Previous chapters discussed functional requirements for the implementation of a trusted path. This chapter will begin with a discussion of some of the key requirements for the trusted path design. These requirements will result in architectural requirements for the design. The trusted path as a state machine will also be introduced. The final section of this chapter presents a set trusted path interfaces to be implemented in order to meet the functional requirements.

### **A. DESIGN REQUIREMENT DISCUSSION**

To prevent some untrusted process from blocking the TCB from receiving the SAK the keyboard scancode should be captured at a low level within the system. This capture should occur inside of the kernel. By keeping the SAK processing in the kernel we can prevent user space processes from affecting the SAK.

Blocking any input/output by untrusted processes while in the trusted path can be accomplished in a number of ways including destroying or suspending any running untrusted processes. Another approach is to isolate the terminal so that only the trusted path can access it. This thesis will suspend user processes to prevent potential spoofing or sniffing.

Ensuring that the authentication process only receives input from the TCB can be accomplished by modifying the traditional *getty* and *login* processes. Both *getty* and the *login* processes currently run in user space.

### **B. ARCHITECTURAL REQUIREMENTS**

The design requirements call for processing in both the kernel and in user space. This drives us toward two separate code modules. One module will be part of the kernel and will be responsible for kernel-related trusted path processing. The other module will be in user space. The functions performed by each module are listed as follows.

### 1. **Trusted Path Kernel Module (TP\_Kern)**

- Catch the SAK
- Suspend user processes
- Restore user processes

### 2. **Trusted Path User Module (TP\_User)**

- Maintain trusted path state
- React to TP\_Kern SAK pressed message
- Control the TTY
- Display initial press SAK message
- Display TP menu
- React to input from TP menu
- Control user authentication
- Start a command shell
- Initialize TTY

## C. **TRUSTED PATH STATES**

From the perspective of a trusted path we can view the computer as a state machine with several distinct states.

### 1. **Stopped**

In the *stopped* state the system is powered down and unavailable for interaction. It will transition to the next state as a result of the boot process. In and of itself this state is not interesting in the context of the trusted path.

### 2. **Awaiting SAK from User**

In the *no\_user* state there are no user processes running on the machine but all of the necessary boot processes have run. The computer is waiting for a user to begin an authentication process. This state will be entered after the system boot process is complete. This state is also entered when a user selects exit to end his session with the computer or when a user incorrectly authenticates.

### 3. **Authentication**

In the *in\_auth* state, the user is proving his identity to the TCB. There are several distinct steps to the authentication but from the perspective of the trusted path it may be

viewed as a single state. Successful completion of the authentication process results in moving to the trusted path menu. Unsuccessful completion results in returning to the *no\_user* state.

#### **4. In the Trusted Path Menu**

In the *in\_TP\_menu* state the user has been authenticated and the trusted path is awaiting user input on his desired action. All user processes are suspended. There are two entry points; this state can be reached by successful completion of the authentication process or by pressing the SAK during the normal execution state. There are also two exit points, the user may exit the trusted path menu to the *user\_run* state or to the *no\_user* state. While in the *in\_TP\_menu* state, the user is authenticated to the system and the trusted path menu is displayed. The trusted path has control of the computer monitor and keyboard.

#### **5. Normal Execution**

The *user\_run* state is the condition in which users may run applications and processes. The user is authenticated to the system and the trusted path is idle.

Figure 1 presents a pictorial representation of the trusted path states and the transitions between the states.

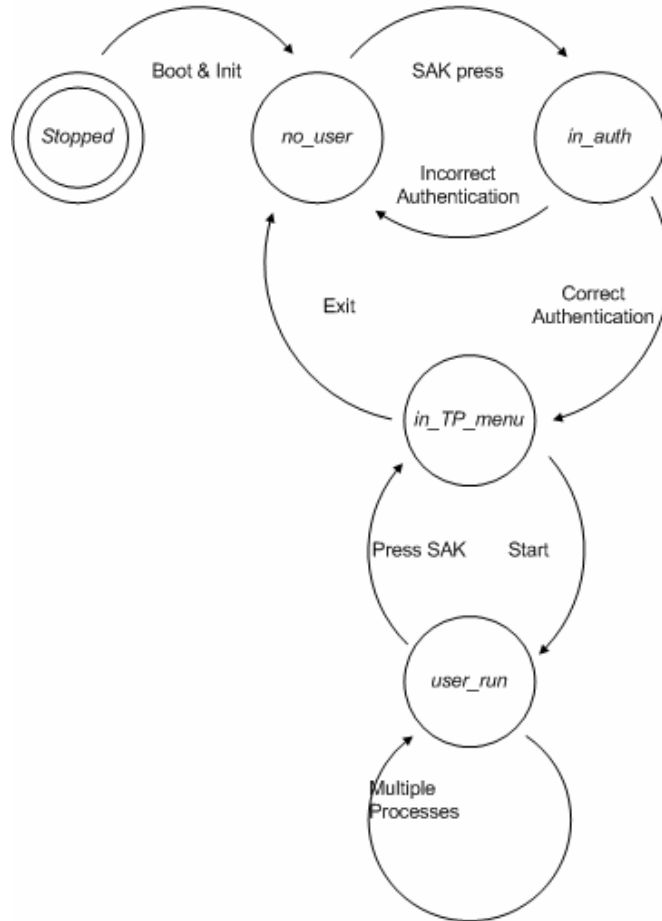

Figure 1. Trusted Path States

#### D. INTERMODULE COMMUNICATION REQUIREMENTS

##### 1. TP\_Kern to TP\_User

Notify Trusted Path User Module that the SAK has been pressed

##### 2. TP\_User to TP\_Kern

Four distinct messages must be sent from the user space trusted path module (UTPM) to the kernel trusted path module (KTPM):

- Register the process ID (PID) of the UTPM with the KTPM. With this information the KTPM can ensure that only the UTPM is making calls to the KTPM. It also will allow the KTPM to signal the UTPM.
- Suspend the processes associated with a particular trusted path ID (TP\_ID). The TP\_ID is the PID of the first user process in the parentage tree of the any given user process.

- Restore the processes associated with a TP\_ID. This is used to restore any previously running processes on returning to a running state from the trusted path menu.
- Kill the processes associated with a TP\_ID. This is used to destroy any user processes when the user exits the system.

## E. TP\_KERN MODULE

TP\_Kern is the kernel space grouping of functionality for the trusted path. It is coded in the `trustedpath.c` as well as the `trustedpath.h` files.

### 1. Interfaces

```
void handle_tp_sak ()
asmlinkage int sys_trustedpath(int type_msg, int pid)
```

The interface was named with a handle prefix because this naming convention is commonly used in the Linux kernel development community.

### 2. Databases

An integer variable, labeled *tp\_id* for trusted path ID, was created in the kernel schedule header file. This variable is used by the fork process to label each process with its *original parent* process ID. In this context, *original parent* is used to describe the first shell process. The *init* process is the only user space process started by the kernel and can be considered the original process in any process tree. The *tp\_id* captures the session level after *tp\_getty* and allows the trusted path to determine which processes are associated with a user session. The *tp\_id* is used to suspend or terminate specific session processes as needed. Detailed information about these modifications are presented in Appendix D, Schedule Header Modification, and Appendix F, Fork Modification. Figure 2 presents a graphic representation of process hierarchy. The *tp\_id* is associated with each session and is derived from the *PID* of the original shell for each session.

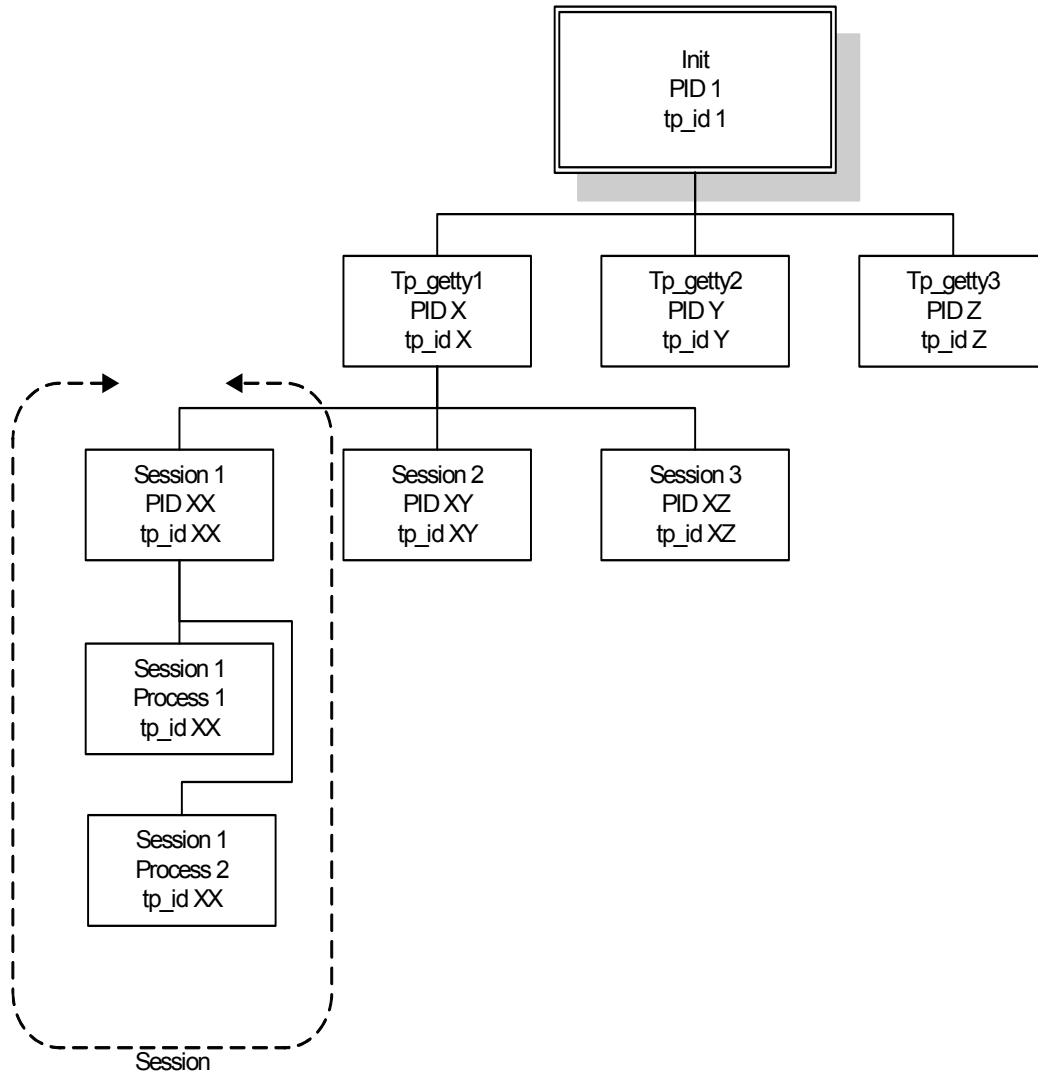

Figure 2. Session Grouping by *tp\_id*.

### 3. TP\_KERN External Interfaces

The following functions are implemented inside of the trusted path kernel module.

#### a. *void handle\_tp\_sak()*

Called by the keyboard driver in response to simultaneous pressing of the control and break keys. TP\_Kern responds to the SAK by notifying the trusted path user space module with a signal.

**b. *asmlinkage int sys\_trustedpath(int type\_msg, int pid)***

This trusted path system call is the user space interface that is used by TP\_User to send information to the TP\_Kern. This function returns a zero on successful completion. There are four messages that were identified as being necessary:

**c. *REGISTER***

Called by the trusted path user module on initialization to pass the trusted path process ID to the TP\_Kern. This information is stored in a kernel variable. This variable is used to allow the TP\_Kern to signal the trusted path process.

**d. *SUSPEND***

Called by TP\_User to suspend all processes with the same tp\_id as the PID that was passed to the function. This is done by suspending each process with a tp\_id that is equal to the tp\_id of the passed in PID. The processes are suspended by removing them from the run queue of the kernel's scheduling process.

**e. *RESTORE***

Called by TP\_User to restore all processes with the same tp\_id as the PID. This is done by determining the tp\_id of the PID. Then each process with this tp\_id is restored by moving the process on the run queue of the kernel.

**f. *KILL***

Called by TP\_User in response to the user ending a session. TP\_kern will then enumerate all the processes associated with the PID's tp\_id and then issue a *force\_sig(SIGKILL,pid)* to each associated PID as defined in signal.c.

**F. TP\_USER MODULE**

The TP\_User module is the user space grouping of functions for the trusted path. It is coded in the *login.c* file which is used to create the *tp\_getty* executable file.

**1. Interfaces**

There are no external interfaces in the traditional sense. The only external input is notification of a SAK from the kernel. This is handled by use of a signal handler in the *tp\_getty* executable.

**2. Databases**

The primary databases to support the trusted path implementation are a state variable and session structure.

The trusted path state variable is labeled *tp\_state* and there are four valid states identified. These are the same states as identified earlier in this section with the exception of the *stopped* state which is not used. The states are:

```
NO_USER
IN_AUTH
IN_TP_MENU
USER_RUN
```

As a user transitions from one state to the next this variable is updated and is used by the *tp\_getty* program to determine the appropriate response to user input.

The session structure maintains information about the user's open sessions.

```
struct session_struct {
    session_tty
    session_pid
    session_fd
} sessions
```

The *session\_struct* is used to capture TTY, PID, and the TTY file descriptor of each session. This information is used to suspend, restore and terminate all the processes associated with a particular user session.

## **G. SUPPORTING MECHANISMS**

The keyboard driver was modified to capture the simultaneous pressing of the control and break keys. This action causes the *handle\_tp\_sak* function to be called in the kernel. The keyboard driver modification is described in Appendix E.

The SE Linux initialization process *init* is modified to start TP\_User. No standard *getty* is started. This modification occurs in the *inittab* file.

## VII. TRUSTED PATH IMPLEMENTATION

### A. INTRODUCTION

The details of the Security Enhanced Linux trusted path implementation are described at a high level in this chapter. Additional implementation details are described in appendices as noted.

### B. CONSOLE TERMINOLOGY

The term console is used in the context of computers with different meanings. Zimmer [26] discusses the origins and history of the term console. According to Zimmer there are at least four meanings of console:

- An instrument panel connected to a computer,
- A display/keyboard unit,
- A display/keyboard unit with additional instrumentation used to monitor system status,
- A display mode for a monitor device.

Additionally, the terms TTY and terminal are commonly used to describe a confined display and keyboard unit. Multiple terminals connected to a single computer used to be the common operating mode. In the early days of computers, these terminals were teletype machines which resulted in the abbreviation of TTY for a terminal.

With the advent of modern desktop computing, the virtual console was developed. Here a single computer and the associated display/keyboard unit have the ability to emulate multiple terminals. For example, in Linux it is common to have multiple virtual consoles that are displayed on a single monitor and which can be toggled between by special keystrokes. Each virtual console can have a different user logged in and may perform different functions.

To further confuse the issue, there is the concept of a terminal window. This is a software program that emulates a terminal inside of a graphic user interface such as *X Windows*.

For the sake of this paper the following definitions of terminal related terms will be used.

*Console* will be reserved for the special case where the primary function of a keyboard/monitor is the administration and/or security of one or more systems.

*TTY* will be used to refer to the logical virtual console. This choice is driven by the TTY construct in Linux, for example, the command *tty* will return the virtual console that the command was entered on.

*Terminal* will be reserved for a physically separate keyboard/monitor that is attached to a computer. In the common desktop computer environment there will only be one terminal per system.

The phrase *terminal window* will describe a terminal emulator inside of a graphical user interface. An example of a terminal window is a program like *gnome-terminal* that provides a *TTY*-like environment as a window inside an X Windows session.

The phrase *computer monitor* will be used to describe the physical display device, e.g., computer CRT or flat panel display unit. The phrase was selected primarily to avoid confusion with the phrase *reference monitor* which is discussed in previous chapters.

### **C. INTERCEPTING OF THE SECURE ATTENTION KEY (SAK)**

Securely intercepting the SAK is critical to providing a trusted path. Once the SAK is pressed the trusted path must always be invoked. Untrusted software must not be able to prevent the trusted path from receiving the SAK notification. In order to achieve this in SELinux, the keyboard driver was modified to notify the kernel module of the trusted path when the SAK keystrokes are made.

*Linux Magic System Request Key* is included in current versions of the Linux kernel and is contained in the *sysrq.c* file. One of the functions that is provided by the *Magic System Request* is a SAK. This implementation of a SAK is very aggressive and essentially kills all of the processes on the TTY. This was not suitable for our implementation of a trusted path. Also the *Magic System Request* did not work at all within *X Windows* on the systems used for this research. Some amount of time was spent

attempting to determine the cause of the *X Window* problem but it was never precisely identified. Both the aggressive nature of the *Magic System Request* SAK and the *X Windows* issue drove the development of a new SAK

The keyboard generates scan codes that indicate what keys have been pressed or released. This information is passed through various hardware specific drivers to the general keyboard driver. All scan codes eventually arrive at the keyboard driver, so this is a logical point at which to insert the SAK detection functionality. Changing or modifying any of the software drivers between the physical keyboard and the keyboard driver requires recompiling and re-installing the kernel which in turn requires root administrative privileges. Assurance that the SAK cannot be intercepted by malicious code is provided because the kernel would require modification to permit this.

The source code of the function which contains the SAK interception code is provided in Appendix E.

#### **D. KERNEL MODULE OF THE TRUSTED PATH**

The trusted path kernel module is primarily a helper set of functionality for the user space trusted path program. This module is a communication channel between the kernel and the trusted path user space program. In addition, it performs some process management.

There are two primary communication systems that are used by this module. For communication from the kernel, signals are used to notify the user space program that a SAK has arrived. Signals are a primitive form of interprocess communication (IPC) and are somewhat limited in their capabilities. More sophisticated methods of IPC were not employed primarily due to the inherent complexity of these methods. This is ultimately becomes a design choice between simplicity and functionality. For this implementation, the simplicity of signals was more important than additional functionality offered by modern IPC methods. The other communication method used in this implementation was a system call for sending messages from the trusted path user space program to the kernel. The trusted path system call is described below.

The kernel module also suspends, restores and terminates processes based on information received by the trusted path system call. The system call provides a process ID (PID) of the group of processes to be suspended, restored or terminated. Using the trusted path ID described below, all of the related processes are identified and the appropriate action is performed by the kernel module. The source code of the trusted path kernel module is provided in Appendix B.

#### **E. CREATION OF A TRUSTED PATH PARENT ID**

In this design all user processes are suspended upon entering the trusted path. A reliable method to identify all the processes associated with a user is required to implement this approach. However, Linux allows changing process parentage information in the process table, *task\_struct*.

To provide the information needed by the trusted path, an additional field was added to the process table. This field is an integer process ID labeled as *tp\_id* for trusted path ID. This field is populated during the *fork* process by the kernel with the *tp\_id* of parent process unless the grandparent process ID (PID) is 1 in which case the *tp\_id* is the current process PID. This will result in all processes associated with a user session having the same *tp\_id*.

The changes to the original Linux source files required for the trusted path parent ID are detailed in Appendix D, Schedule Modification and F, Fork Modification.

#### **F. ADDITION OF A TRUSTED PATH SYSTEM CALL**

The trusted path design consists of two separate groups of code. One group runs in kernel space and the other is a user space construct. To allow the requisite communication to occur, there was a need to build a mechanism for the user space trusted path process to communicate with the kernel. For the sake of simplicity a trusted path system call was implemented. For a discussion on the benefits and disadvantages of using system calls see Love [27].

As identified in the previous chapter, there are four distinct messages that the user space trusted path must be able to send to the kernel:

- Registration of the user space trusted path,
- Suspend user processes,

- Restore user processes, and
- Terminate user processes.

A single system call was designed to allow these four messages be sent to the kernel trusted path mechanism. Detailed implementation information is contained in Appendix C.

## **G. REPLACEMENT OF THE GETTY AND LOGIN PROCESSES**

In the standard SE Linux implementation, the `init` process will start a small number of `getty` processes. In the SE Linux version used for this research, the `getty` program is named `mingetty` because it is a minimal version of a `getty` without some features found in other `getty` programs. `Mingetty` initializes the various TTYs and waits for a user to enter his username. `Mingetty` then `execs` to the `login` program passing the username as a variable. `Login` authenticates the user. *Pluggable Authentication Modules* (PAM) are typically used in modern versions of Linux, including the research version of SE Linux, to perform the authentication.

As discussed in Chapter II, SE Linux uses a security context to limit the behavior of processes. In addition to the standard Linux `user` and `group` identity, the SE Linux security context has an identity, a role and a domain which must be correctly set prior to the user having an interactive shell. If PAM is being used as the authentication method then an additional SE Linux PAM function is used to set the correct security context. After the user is authenticated and appropriate context is set, `login` forks a `bash` shell and the user gains control of the process.

The trusted path implementation replaces `mingetty` and `login` with a trusted path program titled `tp_getty`. This approach to the TTY initialization and user authentication was driven by the state-machine vision of the trusted path described high level design chapter. The vision of the trusted path required the ability of the trusted path to control the state changes which required modification of the process. Another advantage of this process is the reduction in amount of code needed to perform these functions. As an example, in order to support the various authentication methods that are possible, the standard `login` program is in excess of 1400 lines. `Tp_getty` is approximately 500 lines shorter.

The init process starts the number of *tp\_getty* processes determined by the system administrator in the init configuration file, *inittab*. The *tp\_getty* initializes the *ttys* and waits for the user to press the SAK key combination. Once the SAK is pressed *tp\_getty* is notified via a signal sent by the kernel. Then *tp\_getty* uses PAM to authenticate the user. Upon successful authentication, the *tp\_getty* displays the trusted path menu for the user to select the desired action. For this demonstration project the user may select to quit a session, start a new shell or to restore a shell. The behavior of quitting or restoring a session is dependent on the number of open shells. If there is only one open shell then quitting will log the user out of the system otherwise he will be queried as to which shell should be closed. Restoration of a shell displays similar behavior. The total number of permissible open shells is limited to an arbitrary *MAX\_TP\_SHELLS*.

Starting a new shell *forks* a new process, the SE Linux context is set for the new process, and a new *tty* is generated. The SE Linux context is set on each shell that is started from the trusted path menu to allow a user to open multiple shells in different contexts. This is accomplished by using the SE Linux PAM *set\_credentials* function during the *fork* process. After setting the context, the user is switched to the new *tty* and he assumes control of the process. Pressing the SAK key combination while in the user process causes the user's processes to be suspended and the user returns to the *tty* containing the trusted path menu.

There were many challenges to the *tp\_getty* implementation. One was the complexity of the Linux *login* code. To support all the various forms of authentication such as Kerberos, crypto cards, PAM and shadow files a significant number of *#ifdef* statements are included in the code. This is an efficient means of updating or modifying an existing piece of code, but these additions make it more complex and difficult to follow.

The most complex challenge was associated with the SE Linux security policy. SE Linux uses various configuration files to generate policy rules that describe the access permissions for subjects and objects. This research used the NSA example SE Linux security policy which contained in excess of 250,000 rules. Determining how to provide *tp\_getty* with the correct access permissions was time consuming.

In this implementation of the trusted path, the new *tp\_getty* file was given the context of *system\_u:object\_r:login\_exec\_t*. This security context allows *tp\_getty* to fork processes, use PAM modules, reset TTYs and perform other typical login tasks. Also the *init* domain was modified to allow the *init* process to automatically change its security domain to *login\_exec\_t* thus allowing *init* to start the *tp\_getty*. The appropriate configuration files are contained in Appendix H.

## **H. PROCESS SUSPENSION AND RESTORATION**

As part of the design, all user processes must be inactive when the user is interacting with the trusted path menu. This is to prevent the possibility of a user process intercepting any communication between the user and the trusted path.

In order to allow a process to be placed in a suspended state, the process must be removed from the correct run queue which is a data structure that the kernel uses to manage process scheduling. Two additional suspended queues were created in *sched.c* to store the processes that were removed from the run queues. Additionally, the kernel has the ability to temporarily store inactive processes in other queues which required the addition of a *do\_not\_activate* flag in *sched.h*. This combination allows the trusted path to inactivate the user processes. In general, all user processes are suspended prior to allowing access to the trusted path.

After completion of the user interaction with the trusted path, the user may wish to restore a session. This situation is somewhat more complicated than the suspend process because the user may have multiple sessions that are suspended. The user could have zero, one or more than one open session.

If the user selects restore from the trusted path menu but does not have an open session a brief error statement is displayed and the user returns to the trusted path menu. If the user has just one open session then that session is automatically restored. Otherwise, there are multiple open sessions and the trusted path queries the user to determine which session to open.

## **I. CONTROLLING THE TTY**

In this implementation, the trusted path menu is displayed on TTY1. As a user opens new sessions, the session is displayed on next available TTY. In Linux it is

possible for a user to switch between TTYs with certain keystrokes. To prevent the user from switching between a session TTY and the trusted path menu or vice versa it was necessary to block the ability of the user to switch between TTYs by locking the switch functionality. The trusted path controls the active TTY. Trusting the trusted path

The kernel needs to know that the trusted path system calls are indeed coming from the trusted path menu. Otherwise other software could impersonate the trusted path with the potential of denial of service problems. The approach used in this research is simplistic and there is a potential problem. The trusted path menu registers with the kernel prior to the computer becoming available for user input. The kernel then sets a flag to indicate that the trusted path is registered and to prohibit other processes from registering as the trusted path. Once this flag is set it is not possible to reset the trusted path registration.

The kernel uses this registration to validate that each system call is coming from the trusted path by comparing the PID of the calling process against the previously registered PID of the trusted path.

The flaw in this approach is that if the trusted path menu exits due to some error the init process will restart the trusted path menu program but it will not be able to register or signal the kernel. The only remedy in this situation is to reboot the computer system. This is not a robust solution to the problem and requires additional research.

## VIII. TRUSTED PATH TEST PROCEDURES

### A. INTRODUCTION

These test procedures are designed to demonstrate that the trusted path is correctly designed and implemented. The testing will demonstrate the correct implementation of the functional supporting requirements as defined earlier. This chapter describes the test methodology for each of the 10 functional sub-requirements (FSR). An action may test more than one FSR, but, for the sake of completeness, the action will be listed under each FSR that is appropriate.

### B. FSR 1

#### 1. FSR 1 Purpose

The TSF will provide a trusted path menu to allow the user to select the appropriate action to be performed.

#### 2. FSR 1 Testing Rationale

The trusted path menu should always be displayed in three cases. The menu should display after a user has successfully authenticated. It should display when the SAK is pressed in trusted path state *user\_run*. It should also display if an incorrect selection is made from the trusted path menu. The menu should not display at any other time.

#### 3. FSR 1 Test 1

Correctly authenticate to the system in trusted path state *in\_auth*. The trusted path menu should display.

#### 4. FSR 1 Test 2

Incorrectly authenticate to the system in trusted path state *in\_auth*. The trusted path menu should not display.

#### 5. FSR 1 Test 3

Press the SAK while in the trusted path state *user\_run*. The trusted path menu should display.

#### 6. FSR 1 Test 4

Press various key combinations that are not the SAK while in the trusted path state *user\_run*. The trusted path menu should not display.

**7. FSR 1 Test 5**

Press various key combinations that are not the SAK while in the trusted path state *no\_user*. The trusted path menu should not display.

**8. FSR 1 Test 6**

Press the SAK while in the trusted path state *no\_user*. The trusted path menu should not display.

**9. FSR 1 Test 7**

Press various key combinations that are not the SAK while in the trusted path state *in\_TP\_menu*. The trusted path menu should display.

**10. FSR 1 Test 8**

Press the SAK while in the trusted path state *in\_TP\_menu*. The trusted path menu should display.

**11. FSR 1 Test 10**

Press any single key that is not a trusted path menu selection while in the trusted path state *in\_TP\_menu*. The trusted path menu should display.

**B. FSR 2**

**1. FSR 2 Purpose**

The TSF will suspend all non-trusted path user processes associated with the user upon entering the trusted path.

**2. FSR 2 Testing Rationale**

In order to assure that no other process can imitate the trusted path or intercept user-TSF communications, all processes associated with the user should be suspended. This suspension must be complete prior to initiating the trusted path menu. Testing of process states will require additional code to log process status and the time the status changes to determine that all of the necessary processes are suspended prior to initiating the trusted path menu. The test code will execute immediately prior to starting the trusted path menu. The trusted path process is considered to be a system process.

**3. FSR 2 Test 1**

Enter the trusted path menu by successfully authenticating in trusted path state *in\_auth*. The logs should indicate that only system processes are running prior to display of the menu.

**4. FSR 2 Test 2**

Enter the trusted path menu by pressing the SAK in trusted path state *user\_run*. The logs should indicate that only system processes are running prior to display of the menu.

**5. FSR 2 Test 3**

Enter the trusted path menu by selecting any incorrect selection from the trusted path menu in trusted path state *in\_TP\_menu*. The logs should indicate that only system processes are running prior to display of the menu.

**C. FSR 3**

**1. FSR 3 Purpose**

The communication path between the keyboard or computer monitor and the TSF shall be under control of TSF while the trusted path while it is active.

**2. FSR 3 Testing Rationale**

This functional sub-requirement does not readily support automated testing.

**3. FSR 3 Test**

Design and code review will be performed by the Thesis advisors. This review should not reveal any potential communication path vulnerabilities.

**D. FSR 4**

**1. FSR 4 Purpose**

The TSF will always be notified of the secure attention key (SAK) signal.

**2. FSR 4 Testing Rationale**

The TSF must always receive the SAK signal. Some of the following tests will also be conducted while evaluating different FSRs and are repeated here for the sake of completeness or because the desired result may be viewed from a different perspective.

**3. FSR 4 Test**

Press the SAK while in the trusted path state *user\_run*. The trusted path menu should display.

**4. FSR 4 Test 2**

Press various key combinations that are not the SAK while in the trusted path state *user\_run*. The trusted path should not be invoked.

**5. FSR 4 Test 3**

Press the SAK while in the trusted path state *no\_user*. The trusted path authentication process should begin.

**6. FSR 4 Test 4**

Press various key combinations that are not the SAK while in the trusted path state *no\_user*. The trusted path should not be invoked.

**7. FSR 4 Test 5**

Press the SAK while in the trusted path state *in\_auth*. The trusted path login process should restart.

**8. FSR 4 Test 6**

Press various key combinations that are not the SAK while in the trusted path state *in\_auth*. The trusted path should not be invoked and depending on the keys pressed the authentication should fail.

**9. FSR 4 Test 7**

Press the SAK while in the trusted path state *in\_TP\_menu*. The trusted path menu should continue to be displayed.

**10. FSR 4 Test 8**

Press various key combinations that are not the SAK while in the trusted path state *in\_TP\_menu*. The trusted path menu should continue to be displayed.

**E. FSR 5**

**1. FSR 5 Purpose**

User authentication will be controlled via the trusted path.

**2. FSR 5 Testing Rationale**

This functional sub-requirement does not readily support automated testing.

**3. FSR 5 Test 1**

Design and code review will be performed by the Thesis advisors. This review should indicate that the only entry point to the authentication mechanism is through the trusted path.

## **F. FSR 6**

### **1. FSR 6 Purpose**

Pressing the SAK when there is no authenticated user will result in the TSF initiating an authentication sequence.

### **2. FSR 6 Testing Rationale**

These are the same tests as FSR 4 test 3 and FSR 4 test 4.

### **3. FSR 6 Test 1**

Press the SAK while in the trusted path state *no\_user*. The trusted path authentication process should begin.

### **4. FSR 6 Test 2**

Press various key combinations that are not the SAK while in the trusted path state *no\_user*. The trusted path should not be invoked.

## **G. FSR 7**

### **1. FSR 7 Purpose**

Failed authentication will result in returning to the initial *no\_user* state.

### **2. FSR 7 Testing Rationale**

Failed authentication will cause the computer to return to the *no\_user* state and will require the user to begin the process over.

### **3. FSR 7 Test 1**

Incorrectly authenticate to the system in trusted path state *in\_auth*. The message to press the SAK to begin authentication should be displayed.

### **4. FSR 7 Test 2**

Correctly authenticate to the system in trusted path state *in\_auth*. The trusted path menu should display.

## **H. FSR 8**

### **1. FSR 8 Purpose**

Successful authentication will result in the trusted path menu being displayed.

### **2. FSR 8 Testing Rationale**

These are the same tests as in FSR 7.

### **3. FSR 8 Test 1**

Incorrectly authenticate to the system in trusted path state *in\_auth*. The message to press the SAK to begin authentication should be displayed.

### **4. FSR 8 Test 2**

Correctly authenticate to the system in trusted path state *in\_auth*. The trusted path menu should display.

## **I. FSR 9**

### **1. FSR 9 Purpose**

Selecting *run* from the trusted path menu will restore any previously suspended user processes or cause a new shell process to be spawned.

### **2. FSR 9 Testing Rationale**

The trusted path must restore any previously suspended processes upon return to the trusted path *user\_run* state.

### **3. FSR 9 Test 1**

While in the trusted path *user\_run* state initiate some number of processes. Perform a process listing and save the output to a file. Press the SAK and when in the trusted path menu select run to return to the *user\_run* state. Again perform the process listing and save the output to a different file. Compare the two files and the only difference should be the process listing command which might have a different process ID.

## **J. FSR 10**

### **1. FSR 10 Purpose**

Selecting *exit* from the trusted path menu will terminate any user processes and cause the state to change to *no\_user*. The TTY will display the pre-authentication message requesting potential users to press the SAK.

### **2. FSR 10 Testing Rationale**

This will require additional code to generate test results after the user has logged out. This code will log running processes after completing the user logout.

### **3. FSR 10 Test 1**

From the trusted path menu select exit then log back into the system and proceed to the trusted path *user\_run* state. Review the logs to ensure that all user processes were stopped when the *no\_user* state was reached.

## IX. CONCLUSIONS

### A. ANALYSIS AND DISCUSSION

#### 1. The Increasing Complexity of Software

As discussed previously in this paper, the complexity of software increases the likelihood of security relevant issues in the design and implementation. Complexity also decreases the chance that an individual will be able to discover a particular flaw. With enough complexity it may not be possible to determine whether a specific piece of code has a security issue in the larger context of the code it interacts with.

Most software in common usage today is being developed in an incremental fashion. An example of this is the Microsoft Windows XP operating system. The core operating system is modified from Windows 2000 which was modified from Windows NT 4.0. This approach to development is efficient and follows the tenant of code reuse that is promoted by the software development community but typically results in much more complex code. This occurs because additional functionality is inserted into the previous code. This additional code adds features but can significantly increase the complexity of a group of code and in fact can make it much more difficult to understand what are the direct results and side-effects of any given code.

It can be argued that this evolutionary process is the only economical approach to develop large software packages. While this is reasonable, little formal thought is given to the security implications. As the code becomes more complex, the likelihood of significant security problems increases. There is a real economic impact of security issues both in the traditional computer security sense and the more mundane sense of having to pay system administrators to constantly patch and maintain systems.

Linux is a very complex set of software packages. Most of the core kernel functions have been incrementally modified by many authors to offer an increasing number of functions. As an example of this, the scheduling code of the 2.6 kernel is 2,916 lines in contrast to the 849 lines that were in the 1.0.9 kernel. Any particular thread of execution through the scheduler is understandable but the cumulative effects of all the

code makes it difficult to understand the scheduler behavior in a meaningful and holistic sense. This is just one example but the remainder of the kernel contains similar complexity issues. Adding applications software on top of the operating system explodes the difficulty of understanding the security relevant software interactions.

Security Enhanced Linux (SELinux) is a security overlay on the traditional Linux. Security-relevant enforcement mechanisms have been added with one goal being flexibility. The flexibility of the security mechanism significantly increases the complexity of the software. This complexity is in addition to the complexity of the underlying operating system. There is a likelihood approaching certainty that significant security problems exist in this system, though this is not different from other common operating systems.

The Common Criteria [29] mandates the reduction of complexity as a key factor in developing assurance:

Design complexity minimisation contributes to the assurance that the code is understood — the less complex the code in the TSF, the greater the likelihood that the design of the TSF is comprehensible. Design complexity minimisation is a key characteristic of a reference validation mechanism.

The primary purpose of minimizing the complexity of a system is to allow understanding of how the computer system enforces security relevant policy. To state that a computer is high assurance demands that the security relevant functions of the system are understood through the range of potential inputs and the functions will always behave correctly in terms of the security policy. This is the fundamental idea behind the reference monitor concept proposed by Anderson [2]. Related to this complexity issue is the intermingling of security functions with the remainder of the kernel code. With security functions scattered about in thousands of lines of other code, it becomes very difficult to understand the behavior of these functions.

## **2. Security Enhanced Linux**

SELinux is an interesting research project. The addition of mandatory access controls may provide some additional security to the system depending on the SELinux policy used.

The SELinux example policy that is provided by NSA is a very liberal policy that seems to be designed to minimize potential problems for the user. By default, SELinux will deny an action unless that action is specifically allowed in the policy configuration. This is a correct approach to a secure system but in the provided example policy most common actions are specifically allowed. In the example policy provided with this version of SELinux there were in excess of 250,000 rules that permitted actions. In contrast, a typical firewall or VPN implementation may have 100 rules. This implies that a great amount of work would be required to modify this rule set correctly for a given situation.

As long as SELinux is viewed as a research project it has value. It is not high assurance and would have difficulty in being classified even as medium assurance under the Common Criteria. It should not be deployed as a solution in situations that require considerable assurance.

### **3. Adding Security to Existing Systems**

Most of the effort of this project was in understanding the existing implementation of SELinux and the underlying Linux system. Due to the complexity of the current implementation and the lack of design documentation it was difficult to determine how and where to insert pieces of functionality. It was also impossible to determine the potential effects from other parts of the existing code on the new trusted path. This results in some doubt as to the security of the trusted path implementation specifically in terms of potential issues arising from within the kernel. Most of code that was identified as relevant was examined but that only represents a small fraction of the code base and issues such as timing problems were not practical to evaluate. At the core of the issue is that this implementation depends on a tremendous amount of kernel code. The trusted path requires that the kernel behave correctly. This places a great deal of trust in unknown code and programmers.

It is axiomatic that adding security to an existing system is much more expensive than incorporating security from the beginning. This demonstration project demonstrates the truth of this statement. The effectiveness of adding security to existing software decreases as the complexity increases. At some point the complexity becomes

unmanageable and regardless of the efforts to add security very little is accomplished because the existing code base is too large and not understandable with respect to the added security functionality. This statement is empirically demonstrated by the software security patch that results in additional security problems.

These observations imply that any common operating systems in use today will have significant security problems. The code bases of Windows, Linux and Unix are too large and complex to prevent potential security issues. The original implementation of these products did not have security as a primary design consideration. If the lives of DoD personnel depend on the security of data contained in a computer then a high assurance system is needed and none of the listed operating systems will meet the requirements.

## **B. FUTURE WORK**

Ensuring that all trusted path system calls are originating from the trusted path menu requires additional research. The current implementation provides rudimentary security from processes impersonating the trusted path but may require rebooting of the computer if the trusted path menu experiences an error. Additionally, the design of the trusted path identifier, *tp\_id*, is very dependent upon the *task* structure. Further research might provide a more robust implementation mechanism for this identifier.

As currently implemented, the trusted path has been subjected to minimal code review and testing. As a single individual with little oversight it is very possible that this work contains some errors. An extensive code review and more rigorous testing of the implementation must be conducted prior to use of this software in a production system.

## APPENDIX A. TRUSTED PATH –USER SPACE

This is the source code for the trusted path user space module. It is derived from a number of sources. This represents the majority of the coding effort for this demonstration project.

```
// Trusted path user space program
//
// This program acts as the trusted path
// for selinux
//
// This implementation is part of a
// masters thesis
//
// ahilchie
//
// There are major sections which are derived
// from the standard login.c and mingetty.c used by RedHat
//

#include <sys/param.h>

## APPENDIX C. TRUSTED PATH SYSTEM CALL

This appendix provides detailed implementation information for the trusted path system call.

### Adding the interrupt

```
In the arch/i386/kernel/entry.S file add at line 1040
/* system call for the trusted path
 * ahilchie 7-12-04
 */
.long sys_trustedpath      /* 274 */
```

### Adding the stub

```
In the include/asm-i386/unistd.h file add at line 282

#define __NR_trustedpath  274

at line 284 increment the number of valid syscalls
#define NR_syscalls      275
```

### Modifications to trustedpath.h

```
Added access to the system call macro file.
#include <linux/linkage.h>
#define REGISTER 0
#define SUSPEND 1
#define RESTORE 2
#define KILL 3
```

### Modifications to trustedpath.c

```
/* handle trusted path system calls */

asmlinkage int sys_trustedpath( int type_msg, int user_pid){

    switch (type_msg) {
        case REGISTER:
            ...
            break;
        case SUSPEND:
            ...
    }
```

```
        break;
    case RESTORE:
        ...
        break;
    case KILL:
        ...
        break;
    default:
        ...
    }
    return(0);
}
```

### **User space header to support the system call**

Userspace.h

```
#define REGISTER 0
#define SUSPEND 1
#define RESTORE 2
#define KILL 3
```

```
#include <linux/unistd.h>
```

```
_syscall2(int, trustedpath, int, type_msg, int, user_pid);
```

## APPENDIX D. SCHEDULE MODIFICATION

This appendix contains the modifications made to the sched.h and sched.c files in the kernel source tree. Code added as part of this work is in bold face.

### **sched.h**

Due to the size of the original files, only the process table is presented.

The process table, *task\_struct*, was modified to include a new integer process ID for use by the trusted path. This is labeled as *tp\_id* and is used to determine the original parent of processes.

```
struct task_struct {
    volatile long state; /*-1 unrunnable, 0 runnable, >0 stopped*/
    struct thread_info *thread_info;
    atomic_t usage;
    unsigned long flags; /* per process flags, defined below */
    unsigned long ptrace;

    int lock_depth;          /* Lock depth */

    int prio, static_prio;
    struct list_head run_list;
    prio_array_t *array;
    /* DJS - Flag to control the activation of suspended tasks */
    int do_not_activate;

    unsigned long sleep_avg;
    long interactive_credit;
    unsigned long long timestamp;
    int activated;

    unsigned long policy;
    cpumask_t cpus_allowed;
    unsigned int time_slice, first_time_slice;

    struct list_head tasks;
    struct list_head ptrace_children;
    struct list_head ptrace_list;

    struct mm_struct *mm, *active_mm;
};
```

```

/* task state */
struct linux_binfmt *binfmt;
int exit_code, exit_signal;
int pdeath_signal; /* The signal sent when the parent dies */
/* ??? */
unsigned long personality;
int did_exec:1;
pid_t pid;
pid_t __pgrp; /* Accessed via process_group() */
pid_t tty_old_pgrp;
pid_t session;
pid_t tgid;

// trusted path id -- tp_id
// ahilchie 6-16-04
// the true parent pid of this process
// to allow finding all the processes associated with a user

pid_t tp_id;

/* boolean value for session group leader */

if (type != KT_SLOCK)
    kbd->slockstate = 0;
}

```

## APPENDIX F. FORK MODIFICATION

This appendix contains the modification made to the `fork.c` file in the kernel source tree. Code added as part of this work is in bold face. Due to the size of the original files, only the process copy, `copy_process`, function is presented. The `copy_process` is called during the creation of all processes except for the original process `init`.

The modification sets the trusted path identifier, `tp_id`, to the `tp_id` of its parent process unless it's parent is `init`, e.g., process ID 1, in which case the `tp_id` is set to the current process ID. Since `init` will start the `getty` process each time each session has a single unique `tp_id` that is not modified during the course of execution.

```
struct task_struct *copy_process(unsigned long clone_flags,
                                unsigned long stack_start,
                                struct pt_regs *regs,
                                unsigned long stack_size,
                                int __user *parent_tidptr,
                                int __user *child_tidptr)
{
    int retval;
    struct task_struct *p = NULL;

    if ((clone_flags & (CLONE_NEWNS|CLONE_FS)) ==
        (CLONE_NEWNS|CLONE_FS))

## APPENDIX G. INSTALLATION GUIDE

### Installation of Fedora Core 2.2

Boot to CDROM FC 2.2 disk 1  
Graphical install  
Skip CDROM check  
Normal selections e.g. English  
Custom install  
Automatic partitioning with defaults  
Default grup loader  
Default DHCP  
Default firewall  
Active SELinux extensions  
Package selection (just changes from defaults are listed)  
    Editors selected  
    No sound or video  
    No graphics  
    Check all development boxes except KDE  
    Administrative tools  
    System tools  
    No printing support

Edit /etc/inittab to start to at runlevel 3

### Installation of SELinux Policy Files

Rpm -ivh checkpolicy-1-8-1.i386.rpm disk 3  
Rpm -ivh policy-sources-1.9.15.noarch.rpm disk 3

Change the policy files as indicated in Appendix H.

Additionally comment out or remove the following two lines from assert.te  
Line # 44 neverallow { domain -auth -auth\_write } shadow\_t:file ~getattr;  
Line # 115 ifdef(`getty.te', `assert\_execute(getty)')

Rebuild policy by cd /etc/security/selinux/src/policy and using the make install command.

### Linux Configuration

Remove linux services such as sendmail, and all the other unneeded default services.

## Trusted Path Kernel Configuration

Install the trusted path kernel files

Filename	Install location from root of source tree
Trustedpath.h	include/linux/
Trustedpath.c	drivers/char/
Fork.c	kernel/
Keyboard.c	drivers/char/
Keyboard.h	drivers/char/
Sched.h	include/linux/
Sched.c	kernel/

Modify the make file in the drivers/char/ directory to include the trustedpath files e.g. change the following line in the Makefile:

```
obj-y += mem.o random.o tty_io.o n_tty.o tty_ioctl.o pty.o misc.o
```

to read:

```
obj-y += mem.o random.o tty_io.o n_tty.o tty_ioctl.o pty.o misc.o trustedpath.o
```

Make the trusted path system call changes as indicated in Appendix C.

Rebuild kernel

Make xconfig – remove objects that are not needed. As an example, remove pcmcia support.

Make

Echo 0 > /selinux/enforce to temporarily disable SELinux

Make modules\_install

Make install

Modify the boot loader to automatically boot to the new kernel

### Install the login files

Copy the util-login.tgz file to a directory and untar it. Move into the util/login-utils/ directory and issue the make command. Rename the login file as tp\_getty. Move tp\_getty to the desired location and perform the command `chcon system_u:object_r:login_exec_t tp_getty`. This command will set the selinux context of the file correctly.

## APPENDIX H. SE LINUX POLICY CONFIGURATION

This appendix provides the modified policy files that were created for this project.  
The modifications are in bold.

### The login.te file

Typically located in /etc/security/selinux/policy/domains/programs.

```
#DESC Login - Local/remote login utilities
#
# Authors: Stephen Smalley <sds@epoch.ncsc.mil> and Timothy Fraser
# Macroised by Russell Coker <russell@coker.com.au>
# X-Debian-Packages: login
#

#####
#
# Rules for the local_login_t domain
# and the remote_login_t domain.
